ABOUT COVER

Editorial Board Member of *World Journal of Clinical Cases*, Shao-Ping Yu, MD, Associate Professor, Chief Doctor, Department of Gastroenterology and Hepatology, Dongguan Kanghua Hospital, Dongguan 523080, Guangdong Province, China

AIMS AND SCOPE

The primary aim of *World Journal of Clinical Cases* (*WJCC*, *World J Clin Cases*) is to provide scholars and readers from various fields of clinical medicine with a platform to publish high-quality clinical research articles and communicate their research findings online.

WJCC mainly publishes case reports, case series, and articles reporting research results and findings obtained in the field of clinical medicine and covering a wide range of topics including diagnostic, therapeutic, and preventive modalities.

INDEXING/ABSTRACTING

The *WJCC* is now indexed in PubMed, PubMed Central, Science Citation Index Expanded (also known as SciSearch®), and Journal Citation Reports/Science Edition. The 2019 Edition of Journal Citation Reports cites the 2018 impact factor for *WJCC* as 1.153 (5-year impact factor: N/A), ranking *WJCC* as 99 among 160 journals in Medicine, General and Internal (quartile in category Q3).

Propofol pump controls nonconvulsive status epilepticus in a hepatic encephalopathy patient: A case report

Shao Hor, Chih-Yu Chen, Sheng-Ta Tsai

ORCID number: Shao Hor (0000-0001-7032-077X); Chih-Yu Chen (0000-0003-0642-5168); Sheng-Ta Tsai (0000-0001-9932-7801).

Author contributions: Hor S contributed to study conception, data collection, and manuscript writing; Chen CY is the chief doctor of the patient and decided the diagnosis and treatment goal; Tsai ST performed the continuous EEG, made the diagnosis, and initiated this case report.

Informed consent statement: We obtained written informed consent in Chinese from the patient's wife because the patient was initially in a coma and then confusion in following days.

Conflict-of-interest statement: All the authors have no conflict of interest related to the manuscript.

CARE Checklist (2016) statement: The authors have read the CARE Checklist (2016), and the manuscript was prepared and revised according to the CARE Checklist (2016).

Open-Access: This article is an open-access article which was selected by an in-house editor and fully peer-reviewed by external reviewers. Abstract

BACKGROUND

Status epilepticus is an emergent and critical condition which needs management without hesitation. Nonconvulsive status epilepticus (NCSE) tends to be less recognized, and its diagnosis is delayed in comparison with overt status epilepticus because of the absence of specific clinical signs. It is often difficult to make a diagnosis, particularly in patients with hepatic encephalopathy.

CASE SUMMARY

A 38-year-old man with a history of alcoholic liver cirrhosis presented with altered mental status; the initial diagnosis was hepatic encephalopathy. Although optimal treatment for hepatic encephalopathy was administered, the patient's mental status did not improve. A final diagnosis of NCSE was made by continuous electroencephalogram (EEG) monitoring. Treatment with levetiracetam and propofol pump was immediately started. The patient's consciousness gradually improved after discontinuation of propofol therapy, and no further epileptic discharge was observed by EEG monitoring. After 1 wk, the patient returned to full consciousness, and he was able to walk in the hospital ward without assistance. He was discharged with minimal sequela of bilateral conjunctivitis.

CONCLUSION

In cases of persistent altered mental status without reasonable diagnosis, NCSE should be considered in hepatic encephalopathy patients with persistently altered levels of consciousness, and EEG monitoring is very important. We also recommend propofol as a safe and efficient therapy for NCSE in liver cirrhosis.

Core tip: This case highlights the probability of nonconvulsive status epilepticus in patients with liver cirrhosis who do not respond to standard treatment. A multidisciplinary team that includes a neurologist, intensivists, and electroencephalography technicians would contribute to achieving a general improvement in patients with this condition. We also recommend that propofol is a reasonable choice of treatment in such cases.

INTRODUCTION

In the eight-year case series of France^[1], the Brain-Liver team estimated a prevalence of 0.7% for status epilepticus (SE) in patients with cirrhosis [15 of 2010 patients admitted to intensive care unit (ICU)]. And less than three cases (0.15%) could be considered to be non-convulsive SE (NCSE). Although the low incidence, its in-hospital mortality was high (73%). NCSE may not be easily recognized because of the lack of obvious convulsions in comparison with NCSE, and treatment may thus be delayed. It is often difficult to diagnose, particularly in patients with hepatic encephalopathy. Choosing the most appropriate antiepileptic drug in this setting is also challenging because most medications are metabolized by the liver. For example, benzodiazepines are predominantly metabolized in the liver. Valproic acid is mainly eliminated through the liver, and in patients with hepatic diseases, its metabolism could potentially shift to alternative pathways with the production of hepatotoxic metabolites^[2]. Here we report the case of a patient in whom hepatic encephalopathy was strongly suspected and whose ultimate diagnosis was NCSE, which was controlled with a propofol pump. Based on our literature review, this is the first reported case in Taiwan.

CASE PRESENTATION

Chief complaints

A 38-year-old man arrived at our emergency department with acutely altered mental status.

History of present illness

The patient suffered from alcoholism and had a known history of recurrent episodes of hepatic encephalopathy; the most recent episode had happened 5 mo earlier. He had stopped drinking alcohol for 5 mo and had started drinking again 1 wk prior to this presentation. On the morning of admission, the family had incidentally found him lying in bed, confused and lethargic, and immediately called an ambulance.

History of past illness

The patient did not have any history of disease and did not have a history of seizures or brain trauma, and he had not recently undergone surgery.

Personal and family history

The patient has been drinking alcohol everyday for 16 years. Family history was not contributory.

Physical examination upon arrival

Upon arrival, the patient had a blood pressure of 96/56 mm Hg, pulse rate of 132 beats per minute, body temperature of 37.5 °C, respiratory rate of 22 breaths per min, and oxygen saturation of 96% in room air. Physical examination revealed no acute distress and a Glasgow Coma Scale score of 5 (eyes, 1; verbal, 3; and motor, 1). No signs of trauma were observed on his body. His pupils were equal in size, round, and nonreactive to light. Cardiopulmonary and abdominal examination findings were unremarkable. Bilateral Babinski signs were absent, but the neurological examination otherwise was limited because the patient could not follow commands.

Laboratory examinations

Laboratory studies showed a white blood cell count of 9900/ μ L with 75.8% of neutrophils, hemoglobin level of 17.6 g/dL, hematocrit of 50.6%, and platelet count of 117000/ μ L. Electrolyte, liver function, and blood chemistry results were as follows: Sodium, 132 mmol/L; potassium, 3.5 mmol/L; calcium, 8.2 mg/dL; magnesium, 2.4 mg/dL; blood urea nitrogen, 34 mg/dL; creatinine, 2.72 mg/dL; total bilirubin, 6.7 mg/dL; direct bilirubin, 3.8 mg/dL; alanine aminotransferase, 496 IU/L; alkaline phosphatase, 163 IU/L; albumin, 3.9 g/dL; lipase, 73 IU/L; prothrombin time (international normalized ratio), 1.17; and ammonia, 277.7 μ mol/L (reference range, 6–47 μ mol/L). The fasting blood glucose level was 168 mg/dL; the lactate level was 71.5 mg/dL. The arterial blood gas pH was 7.29 (partial pressure of carbon dioxide, 56 mm Hg; partial pressure of oxygen, 71 mm Hg; and actual bicarbonate level, 26.9 mmol/L).

Imaging examinations

Electrocardiograms and chest radiographs revealed no acute pathological finding. Brain computed tomography without contrast enhancement revealed no hemorrhage or acute ischemic stroke. Abdominal computed tomography showed atelectasis in both lower lung zones, fatty liver, and ileus.

Clinical course

In the emergency department, one episode of generalized seizure with frothing at the mouth and both eyes deviated to the left side lasting for several minutes was noted. An intravenous injection of lorazepam (1 ampoule of 2 mg) was immediately administered for seizure control; at that time, the patient's Glasgow Coma Scale score was 3 (eyes, 1; verbal, 1; and motor, 1). The patient was intubated and admitted to an ICU for monitoring with a diagnosis of hepatic encephalopathy. Lorazepam and vitamin B infusion were administered to prevent alcohol withdrawal syndrome; lactulose (30 mL) *via* a nasogastric tube was administered three times per day for management of hepatic encephalopathy, and broad-spectrum empirical antibiotics were administered for control of any infection. On the second day of his hospitalization, several episodes of involuntary bilateral feet dorsiflexion were noted. His ammonia level decreased to 88.1 μ mol/L by the third day of hospitalization, but intermittent involuntary movement in the lower face was still noted.

MULTIDISCIPLINARY EXPERT CONSULTATION

A neurologist was consulted; a bedside electroencephalogram (EEG) was performed, which revealed intermittent spike-and-wave patterns, predominantly in the right hemisphere (Figures 1 and 2).

FINAL DIAGNOSIS

Nonconvulsive SE.

TREATMENT

We intravenously administered levetiracetam (1 vial) every 12 h and initiated propofol pump infusion. We adjusted the dosage of propofol based on continuous EEG monitoring. The formal EEG (International 10–20 system) was obtained one day later, while the patient was under propofol sedation. It did not show epileptic discharge. We started to taper down the dose of propofol after 40 h of infusion, and no more spike-and-wave pattern was noted on the bedside EEG monitor.

Figure 1 Some spike-and-wave complexes (white boxes) at electroencephalogram 2, not synchronized with the heart-beat, favoring epileptiform discharge, predominant at the right hemisphere, about 0.58 Hz. HR: Heart rate; SpO2: Saturation of oxygen measured with a pulse oximeter; NBP: Non-invasive blood pressure.

OUTCOME AND FOLLOW-UP

The patient became alert and oriented, and he achieved a Glasgow Coma Scale score of 15 (eyes, 4; verbal, 5; and motor, 6) on the 12th day of hospitalization. The endotracheal tube was successfully removed. The patient was subsequently transferred to an ordinary hospital ward, and he demonstrated that he could walk around without assistance. On the 18th day of hospitalization, the patient was discharged and continued to do well on subsequent follow-up monitoring.

DISCUSSION

First of all, the most important is the diagnosis of NCSE. According to the 2015 Salzburg Electroencephalography Consensus Criteria for NCSE^[3] (Table 1), our patient had epileptiform discharge (ED) $\leq 2.5/s$ (around 0.58 Hz, Figure 1). So we need to find additional criteria to make the diagnosis. Our patient got some involuntary movements (bilateral feet subtle dorsiflexion) during the ICU. It fulfilled the subtle clinical ictal phenomena. But according to the previous study published by Rudler *et al*^[1], some abnormal movements are non-epileptic, which are easy to be misdiagnosed as SE. Therefore, we checked the continuous EEG monitor during the patient's feet movements. The EEG monitor showed spike and wave complex at that time, instead of triphasic wave (characteristic of hepatic encephalopathy). Also the EEG of the patient had no reactivity to external stimulus (favoring epileptiform discharge). Because of the above reasons, we diagnosed this case as NCSE according to the EEG monitoring (we cannot perform the 10-20 EEG at that time because of the limitation of facility). And the clinical improvement by propofol pump supported our diagnosis. In addition, some specific findings in diffusion-weighted imaging sequences of magnetic resonance imaging (MRI) (cortical or subcortical hyperintensity) may also support the diagnosis of SE^[4]. In our case, the consciousness of the patient recovered to his usual status without sequela. We did not perform brain MRI for him. We consider to arrange the MRI examination a few months later for follow-up.

We found three similar case reports (Table 2) in the literature. In these case reports, patients with underlying hepatic diseases presented with symptoms of hepatic encephalopathy, but NCSE was later confirmed by EEG^[5-7]. As in our case, the mental status of those patients did not improve despite optimal medical treatment and a decrease in ammonia level. In each case, after the multidisciplinary team discussed patient's clinical conditions, the neurologist made a final diagnosis of NCSE by bedside continuous EEG monitoring; treatment was immediately started. These cases told us that in cases of unexplained alteration in mental status like our situation, NCSE should be considered, and EEG should be immediately obtained^[8,9].

About the treatment, we chose propofol because of its safety in patients with hepatic failure^[10,11]. However, we were concerned about propofol infusion syndrome, which is characterized by cardiac failure, rhabdomyolysis, severe metabolic acidosis, and renal failure, and may occur if duration of treatment is longer than 48h^[12]. We discontinued the propofol infusion after 40 h to prevent this syndrome. We also regularly checked our patient's venous gas, creatine kinase, blood urea nitrogen, and creatinine values.

Figure 2 The positions of five electrodes on the scalp. EEG: Electroencephalogram; FP1: Front point 1, 1 cm above the midline of left eyebrow; FP2: Front point 2, 1 cm above the midline of right eyebrow; T3: Temporal point 3, 1 cm above the left ear tip; T4: Temporal point 4, 1 cm above the right ear tip; Ground: Ground electrode, 1 cm above the nasion.

Our patient benefited from early multidisciplinary team intervention and immediate EEG monitoring. In a referral center, a multidisciplinary team that includes a neurologist, intensivists, and electroencephalography technicians would contribute to achieve a general improvement in patients with this condition.

CONCLUSION

In an evaluation of patients with liver cirrhosis who present with change of consciousness, it is important to consider the possibility of NCSE, particularly in patients who do not respond to standard treatment. And the EEG is the examination of choice to get the prompt diagnosis of SE. We also believe that propofol is a reasonable choice of treatment in such cases.

Table 1 2015 Salzburg Electroencephalography Consensus Criteria for nonconvulsive status in patients without preexisting epileptic encephalopathy**2015 Salzburg Electroencephalography Consensus Criteria**

Epileptiform discharge > 2.5/s

Or

Epileptiform discharge ≤ 2.5/s and at least one of the additional criteria:

1 Clinical and EEG improvements from antiepileptic drugs

2 Subtle clinical ictal phenomena

3 Typical spatiotemporal evolution

EEG: Electroencephalography.
