## **SPECIFIC COMMENTS TO AUTHORS**

Human cystic echinococcosis (CE), or designated as hydatid cyst disease, refers to a zoonosis caused by the larval cestode *Echinococcus granulosus*. Currently, the disease remains endemic in sheep-raising areas of the world as the sheep are the major intermediate host. Residents of the sheep-raising area can be infected incidentally. The most frequent site for the cystic lesions observed in the cystic echinococcosis is liver, followed by lung, brain and other organs. Hepatocellular carcinoma (HCC), one of the most common types of cancer in China including Xinjiang, is always secondary to either a viral hepatitis infection (i.e. hepatitis B or C) or cirrhosis. To date, the association between these two diseases was still not fine defined due to lack of clinical evidences. Author concluded that our study may raise the possibility that human CE may induce the development and metastasis of HCC in human beings. I ask some questions to author. 1. Please tell me the etiology which human CE may induce the development and metastasis of HCC in human beings. 2. Are there many patients with *Echinococcus* in this area?

#### **SPECIFIC COMMENTS TO AUTHORS**

- The idea of the paper are good. but i think you must write how many cases are reported in the literature and you can do a small review about these cases. also, can you put anther photo ( high power ) for histopathology of HCC as your photo is not clear.
