Posttransplant erythrocytosis - Kidney International

[https://www.kidney-international.org/article/S0085-2538\(15\)48996-3/fulltext](https://www.kidney-international.org/article/S0085-2538(15)48996-3/fulltext)

Posttransplant erythrocytosis (PTE) is defined as a persistently elevated hematocrit to a level greater than 51% after renal transplantation. It occurs in 10% to 15% of graft recipients and usually develops 8 to 24 months after engraftment.

Posttransplant erythrocytosis - PubMed

<https://pubmed.ncbi.nlm.nih.gov/12631334>

Posttransplant erythrocytosis (PTE) is defined as a persistently elevated hematocrit to a level greater than 51% **after renal transplantation**. It occurs in 10% to 15% of graft recipients and usually develops 8 to 24 months after engraftment. Spontaneous remission of established **PTE** is observed in one fourth of the patients within 2 years from onset, whereas in the remaining three fourths it persists for several years, ...
