Brian M Fung, Keith D Lindor, James H Tabibian

### Abstract

Primary sclerosing cholangitis (PSC) is a rare cholestatic liver disease characterized by progressive fibroinflammatory destruction of the intra- and/or extrahepatic biliary ducts. While its features and disease course can be variable, most patients with PSC have concurrent inflammatory bowel disease and will eventually develop liver cirrhosis

The presence of PSC heightens the risk for colorectal carcinoma in patients with IBD by severalfold. The cumulative risk of developing colorectal neoplasia has been reported to be 50% after 25 years of disease in patients with PSC-IBD compared to only 10% after 25 years of disease in patients with IBD alone.
