COMMENTS TO AUTHORS

Anti-N-methyl-D-aspartate receptor encephalitis (ANMDARE) is an uncommon autoimmune disorder with a wide spectrum of neuropsychiatric symptoms. Psychiatric and neurological disorders are typical features for NMDAR encephalitis in young adults. In this manuscript, the authors presented a rare case of ANMDARE in which the patient aggravated after acinetobacter baumannii pneumonia and well responded to immunotherapy. Although an interesting case, there are several matters to be addressed before this paper is suitable for publication. 1. Previous work by Qi Huang et al. has shown that adults more frequently suffered from status epilepticus and pneumonia. Adults exhibit worse outcomes mostly because of status epilepticus but not pneumonia. In this paper, the author concluded that acinetobacter baumannii pneumonia can aggravate the process of ANMDARE. A more detailed discussion of a potential link as well as the mechanism underlying this association should be added. 2. Produce 2-3 figures and tables and so that paper is easier to read and data (such as CSF, imaging

COMMENTS TO AUTHORS

this is an interesting case report. I suggest only minor changes I suggest to add reference to the sentences: Following a growing attention paid to this disease, an increasing number of reports and analyses have appeared in recent years. Acinetobacter baumannii pneumonia has rarely been described in patients with ANMDARE. I suggest to add a figure to the sentence: Computerized tomography (CT) in the chest revealed acute lung inflammation;
