**ABOUT COVER**

Editorial board member of *World Journal of Gastroenterology*, Chang Moo Kang, MD, PhD, Associate Professor, Division of Hepatobiliary and Pancreatic Surgery, Department of Surgery, Yonsei University, Pancreaticobiliary Cancer Clinic, Yonsei Cancer Center, Severance Hospital, Seoul 120-752, South Korea

**AIMS AND SCOPE**

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a peer-reviewed open access journal. *WJG* was established on October 1, 1995. It is published weekly on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup>, and 28<sup>th</sup> each month. The *WJG* Editorial Board consists of 642 experts in gastroenterology and hepatology from 59 countries.

The primary task of *WJG* is to rapidly publish high-quality original articles, reviews, and commentaries in the fields of gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, hepatobiliary surgery, gastrointestinal oncology, gastrointestinal radiation oncology, gastrointestinal imaging, gastrointestinal interventional therapy, gastrointestinal infectious diseases, gastrointestinal pharmacology, gastrointestinal pathophysiology, gastrointestinal pathology, evidence-based medicine in gastroenterology, pancreatology, gastrointestinal laboratory medicine, gastrointestinal molecular biology, gastrointestinal immunology, gastrointestinal microbiology, gastrointestinal genetics, gastrointestinal translational medicine, gastrointestinal diagnostics, and gastrointestinal therapeutics. *WJG* is dedicated to become an influential and prestigious journal in gastroenterology and hepatology, to promote the development of above disciplines, and to improve the diagnostic and therapeutic skill and expertise of clinicians.

**INDEXING/ABSTRACTING**

*World Journal of Gastroenterology* (*WJG*) is now indexed in Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports®, Index Medicus, MEDLINE, PubMed, PubMed Central and Directory of Open Access Journals. The 2017 edition of Journal Citation Reports® cites the 2016 impact factor for *WJG* as 3.365 (5-year impact factor: 3.176), ranking *WJG* as 29<sup>th</sup> among 79 journals in gastroenterology and hepatology (quartile in category Q2).

### Abstract

#### AIM

To identify multiple microRNAs (miRNAs) for predicting the prognosis of gastric cancer (GC) patients by bioinformatics analysis.

#### METHODS

The original microarray dataset GSE93415, which included 20 GC and 20 tumor adjacent normal gastric mucosal tissues, was downloaded from the Gene Expression Omnibus database and used for screening differentially expressed miRNAs (DEMs). The cut-off criteria were  $P < 0.05$  and fold change  $> 2.0$ . In addition, we acquired the miRNA expression profiles and clinical information of 361 GC patients from The Cancer Genome Atlas database to assess the prognostic role of the DEMs. The target genes of miRNAs were predicted using TargetScan, miRDB, miRWalk, and DIANA, and then the common target genes were selected for functional enrichment analysis.

#### RESULTS

A total of 110 DEMs including 19 up-regulated and 91 down-regulated miRNAs were identified between 20 pairs of GC and tumor adjacent normal tissues, and the Kaplan-Meier survival analysis found that a three-miRNA signature (miR-145-3p, miR-125b-5p, and miR-99a-5p) had an obvious correlation with the survival of GC patients. Furthermore, univariate and multivariate Cox regression analyses indicated that the three-

miRNA signature could be a significant prognostic marker in GC patients. The common target genes of the three miRNAs are added up to 108 and used for Gene Functional Enrichment analysis. Biological Process and Molecular Function analyses showed that the target genes are involved in cell recognition, gene silencing and nucleic acid binding, transcription factor activity, and transmembrane receptor activity. Cellular Component analysis revealed that the genes are portion of nucleus, chromatin silencing complex, and TORC1/2 complex. Biological Pathway analysis indicated that the genes participate in several cancer-related pathways, such as the focal adhesion, PI3K, and mTOR signaling pathways.

### CONCLUSION

This study justified that a three-miRNA signature could play a role in predicting the survival of GC patients.

**Key words:** Gene functional enrichment; Prognosis; Bioinformatic analysis; Differentially expressed miRNAs; Gastric cancer

© **The Author(s) 2018.** Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** We identified 110 differentially expressed miRNAs through mining the datasets of Gene Expression Omnibus database and acquired the miRNA expression profiles and clinical information of 361 gastric cancer (GC) patients from The Cancer Genome Atlas database. Multiple miRNAs together acting as biomarkers may have a stronger reliability in survival prediction. Our study found that a novel three-miRNA signature could be used for predicting the prognosis of GC patients.

Three-microRNA signature identified by bioinformatics analysis predicts prognosis of gastric cancer patients. *World J Gastroenterol* 2018; 24(11): 1206-1215 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v24/i11/1206.htm> DOI: <http://dx.doi.org/10.3748/wjg.v24.i11.1206>

## INTRODUCTION

Gastric cancer (GC) is the fourth most common cancer in incidence and the second in mortality among all cancers worldwide<sup>[1]</sup>. In 2008, a total of 989600 individuals were newly diagnosed with GC and 738,000 deaths occurred, therefore, this disease is a serious public health issue worldwide<sup>[2]</sup>. Research studies that explore the cellular and molecular mechanisms of GC development and the validation of novel biomarkers are urgently needed to achieve early diagnosis and treatment.

MicroRNAs (miRNAs), which are endogenous small

noncoding RNAs (20-22 nt), have been identified as the key regulators of genes at the post-transcriptional level<sup>[3]</sup>. Increasing studies have found that miRNAs are associated with the development and progression of GC, and can act as important biomarkers in diagnosis<sup>[4,5]</sup>, therapy<sup>[6]</sup>, and prognosis<sup>[7,8]</sup>. Thus, the identification of differentially expressed miRNAs (DEMs) may contribute to the early diagnosis and the prediction of survival prognosis in GC.

Several studies have found that a number of miRNAs are differentially expressed in GC and are associated with survival prognosis. However, these studies lack a large sample size or an appropriate proportion of samples. A reliable survival prediction requires large-scale samples that include detailed clinical characteristics. The Gene Expression Omnibus (GEO) database is a public functional genomics data repository that includes array- and sequence-based data and allows users to query and download experiments or curated gene expression profiles<sup>[9]</sup>. The Cancer Genome Atlas (TCGA, <http://cancergenome.nih.gov>) project is one of the most useful cancer genomics programs and has generated, analyzed, and made available genomic sequence, expression, methylation, and copy number variation data on over 11000 individuals who represent over 30 different types of cancer<sup>[10]</sup>. In the present study, we identified DEMs between GC and adjacent normal tissues by analyzing the miRNA data of GSE93415 from GEO. In addition, the associations between DEMs and survival prognosis were analyzed using the expression profiles and clinical features downloaded from TCGA.

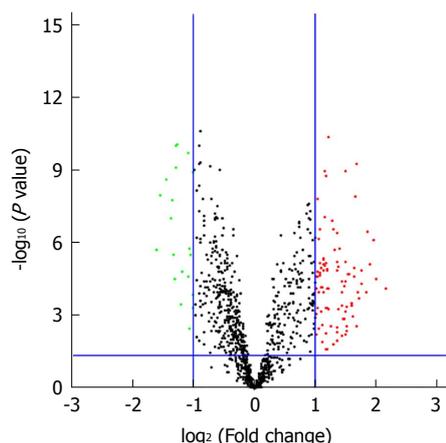

## MATERIALS AND METHODS

### Microarray data processing and DEMs identification

The microarray data of GSE93415 were downloaded from the GEO database (<https://www.ncbi.nlm.nih.gov/geo/>) and the miRNA expression data were processed with the limma package in R. Statistically significant DEMs between GC and adjacent normal samples were identified with the cut-off criterion  $P < 0.05$  and fold change  $> 2.0$ .

### Association analysis between DEMs and GC patients' survival

TCGA (<https://cancergenome.nih.gov/>) stomach adenocarcinoma and adjacent normal tissue miRNA sequencing data and clinical information were downloaded for analysis. The inclusion criteria included: (1) samples with completed data for analysis; (2) patients had not received preoperative chemoradiation; and (3) overall survival time less than 80 mo. Consequently, 361 GC samples were included in the present study. The Kaplan-Meier method and log-rank test were conducted to test the prognostic value of DEMs. When  $P < 0.05$ , miRNAs were considered significantly associated with

**Figure 1** The volcano plot of the differentially expressed miRNAs. A total of 110 DEMs were identified between 20 pairs of GC patients and adjacent normal tissues (cut-off criteria are  $P < 0.05$  and fold change  $> 2.0$ ). The green and red spots represent downregulated and upregulated miRNAs, respectively. DEMs: Differentially expressed miRNAs; GC: Gastric cancer.

the prognosis of patients. Then, we ranked prognosis-related miRNAs according to the median expression level. Subsequently, we scored each GC patient in accordance with a high or low level of expression, and a risk grade was defined by the total scores. Finally, GC patients were sorted into high and low risk groups by the risk-score rank. The prognosis-related miRNA signature was used to analyze overall survival between high and low risk group patients using a Kaplan-Meier curve.

#### Target genes prediction of prognostic DEMs

We used four online tools to predict the potential target genes of the prognostic related DEMs, including TargetScan ([http://www.targetscan.org/vert\\_71/](http://www.targetscan.org/vert_71/)), miRDB (<http://www.mirdb.org/>), miRWalk (<http://zmf.umm.uni-heidelberg.de/apps/zmf/mirwalk2/index.html>), and DIANA (<http://www.microna.gr/microT-CDS>). In order to obtain the more reliable target genes, the Venn plot was performed to acquire the consensus genes of the four online tools.

#### Function analysis of target genes

FunRich [Functional Enrichment analysis tool (<http://www.funrich.org/>)] is a stand-alone software used for functional enrichment and interaction network analysis of genes and proteins<sup>[11]</sup>. Enrichment analysis was conducted on the consensus genes using the FunRich tool in the following categories: Biological Process, Cellular Component, Molecular Function, and Biological Pathways.  $P < 0.05$  was considered statistically significant.

#### Statistical analysis

The data of miRNA expression in GC and adjacent normal samples were performed by unpaired *t*-test. The association between DEMs expression and

clinical characteristics was analyzed by the chi-square and *t*-tests. Kaplan-Meier survival analysis and the univariate/multivariate Cox regression analysis were used to assess the expression levels of DEMs and prognostic features. All the statistical analyses were performed with IBM SPSS version 19.0 and  $P < 0.05$  was considered statistically significant.

## RESULTS

### Identification of DEMs in GC

The microarray data of GSE93415, including 20 pairs of GC and adjacent normal tissue samples, were obtained from the NCBI-GEO database. After applying cut-off criteria of  $P < 0.05$  and fold change  $> 2.0$ , a total of 110 DEMs were identified between GC and adjacent normal tissues (Table 1). The results of 19 downregulated miRNAs and 91 upregulated miRNAs are displayed in the volcano plot (Figure 1). A heat map of hierarchic cluster analysis showed that DEMs could be discriminated between GC and normal tissues (Figure 2).

### Identification of DEMs related with overall survival in GC

To identify the DEMs which could be used to predict the overall survival of GC patients, we collected 361 samples from TCGA to assess the relationship between DEMs and the overall survival of GC patients. The patients' clinical characteristics including age at diagnosis, gender, race, TNM stage, and histologic grade are shown in Table 2. By using a log-rank test and Kaplan-Meier curve, we found that three DEMs (miR-145-3p, miR-125b-5p, and miR-99a-5p) were negatively associated with overall survival (Figure 3). The association analysis between the three DEMs and clinical characteristics indicated that miR-145-3p, miR-125b-5p, and miR-99a-5p were all significantly associated with histologic grade ( $P < 0.05$ ). The detailed results are shown in Table 3.

### Prognostic role of a three-DEM signature in GC patients

We ranked the three DEMs by the median of expression and then scored each GC patient in accordance with high or low-level expression. A risk grade was defined by the total scores. As a result, all the 361 GC patients were sorted into a high or low risk group. A survival analysis with the Kaplan-Meier method and log-rank test was conducted. The results indicated that the overall survival between the high risk and low risk groups was significantly different ( $P = 0.045$ ). Interestingly, compared to patients in the high risk group, the low risk patients tended to have a better prognosis (Figure 4). Furthermore, we performed univariate and multivariate Cox regression analyses to verify the prognostic role of the three-DEM signature according to clinical features. The univariate analysis showed that pathologic stage (HR = 1.825,  $P < 0.001$ ), T stage (HR = 1.864,  $P = 0.006$ ), N stage (HR = 2.005,  $P = 0.001$ ), and the three-DEM signature (HR = 1.422,

<sup>1</sup>Upregulated DEMs are listed according to the rank of fold changes. DEMs: Differentially expressed miRNAs.

$P = 0.039$ ) were significantly associated with the prognostic outcome of GC patients. The multivariate analysis revealed that T stage (HR = 1.623,  $P = 0.044$ ) and the three-DEM signature (HR = 1.451,  $P = 0.032$ ) were all independent factors in predicting the prognosis of GC patients (Table 4).

### Target prediction of three DEMs and gene function analysis

The online target prediction tools TargetScan, miRDB, miRWalk, and DIANA were used to predict the targets genes of miR-145-3p, miR-125b-5p, and miR-99a-5p. We then obtained the consensus genes of each DEM from the four online predictions (Figure 5). As a result, we identified a 108 consensus target genes. Furthermore, we conducted gene enrichment analysis to identify the biological function of common target genes (Figure 6). The Biological Process analysis indicated that the genes were mostly enriched in cell recognition, regulation of nucleic acid, and gene silencing. Cellular Component analysis indicated that genes were enriched in the nucleus, RNA-induced silencing complex,

chromatin silencing complex, and phosphoinositide 3-kinase complex. Molecular Function analysis showed that genes were enriched in transmembrane receptor, transcription regulator, and transcription factor activity. Biological Pathways were mainly enriched in the VEGFR, PI3K/Akt, and mTOR signaling pathways.

## DISCUSSION

Due to the reduction in chronic *Helicobacter pylori* infection and improvement of sanitation, the incidence and mortality rates of GC have declined in recent years<sup>[12]</sup>. However, there are still almost 460,000 new GC cases and 350000 GC deaths each year in China<sup>[13]</sup>. The prognosis of GC patients is poor and the five-year survival rate is 5%-20% despite advances in GC therapy<sup>[14]</sup>. Thus, to improve the clinical treatment and management of GC patients, it is urgent to identify reliable prognostic biomarkers. In this study, we identified a total of 110 DEMs by analyzing the GSE93415 data and discovered that three miRNAs (miR-145-3p, miR-125b-5p, and miR-99a-5p) were

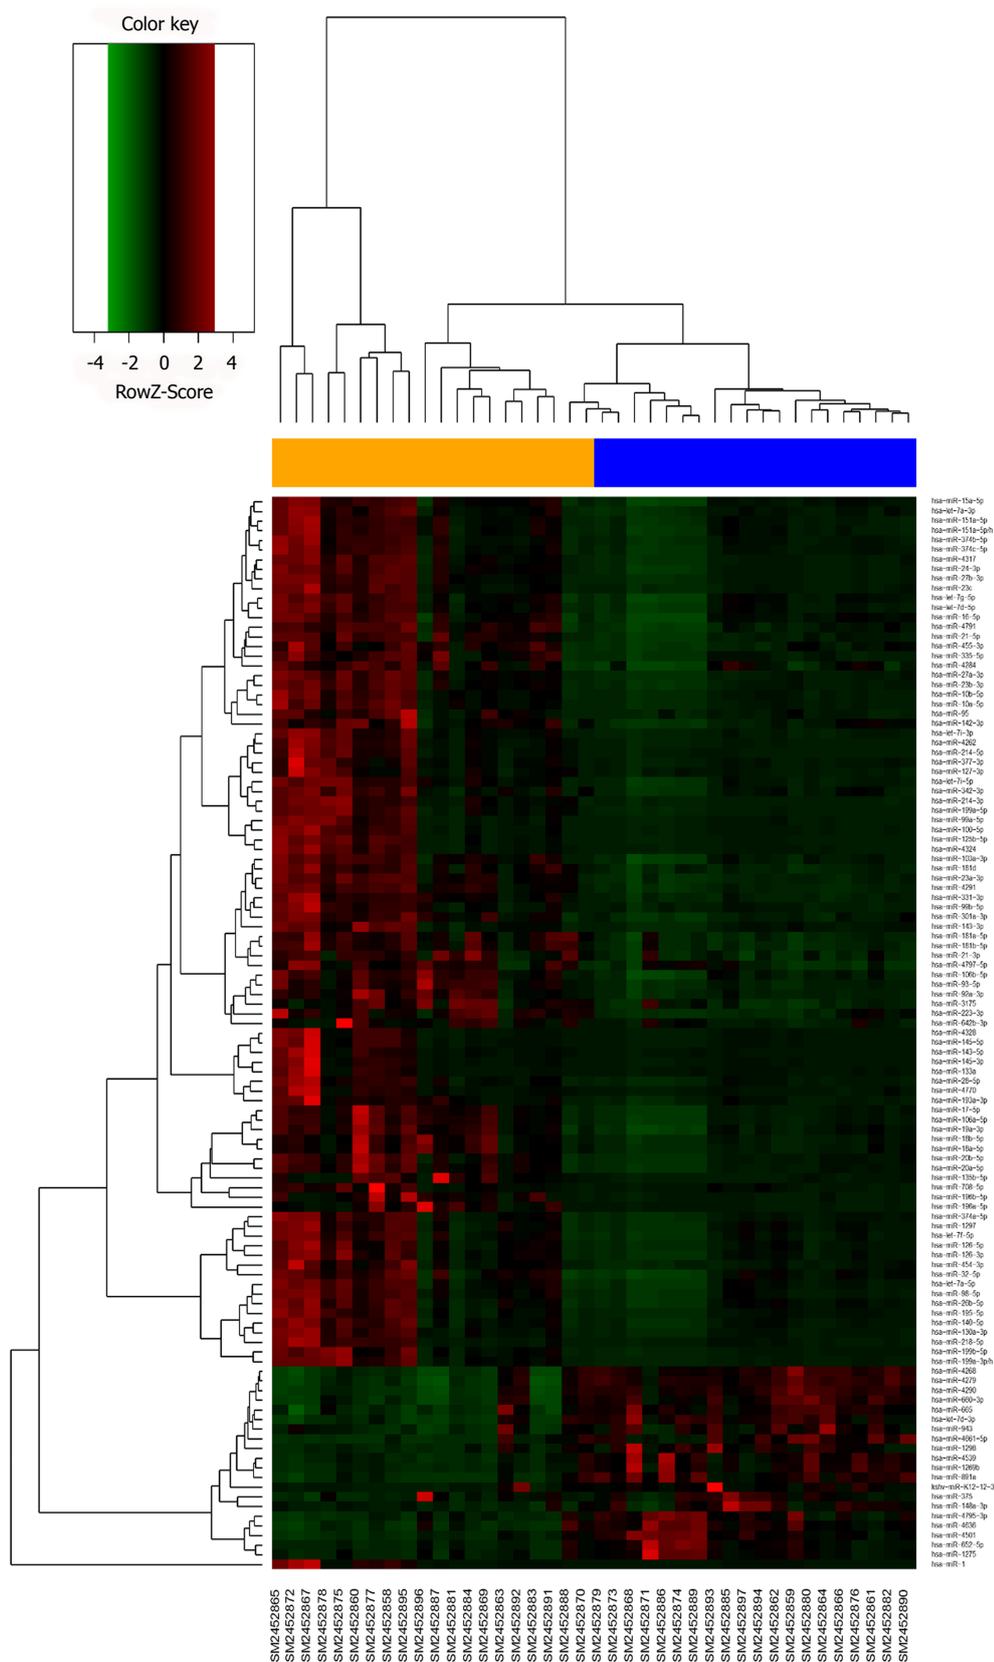

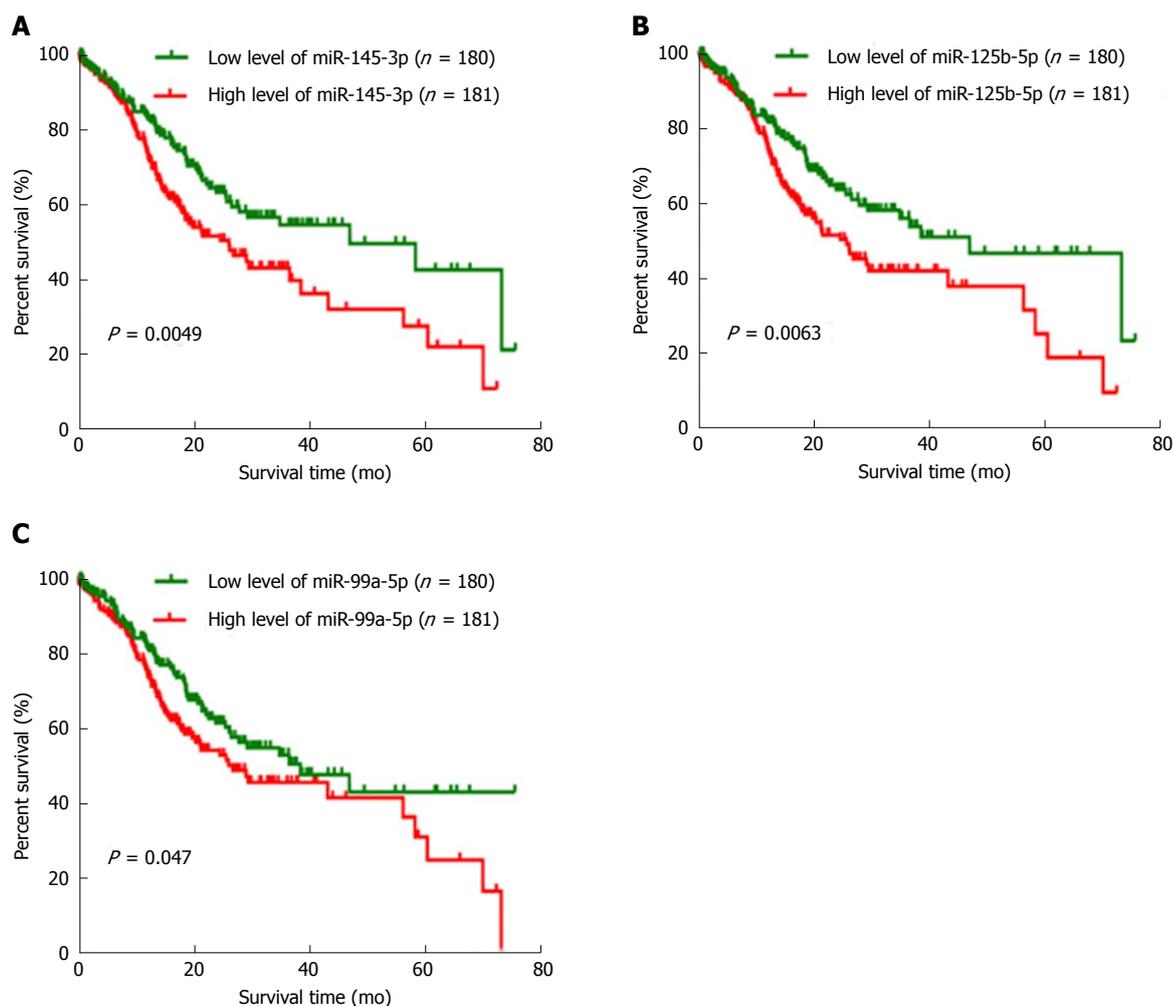

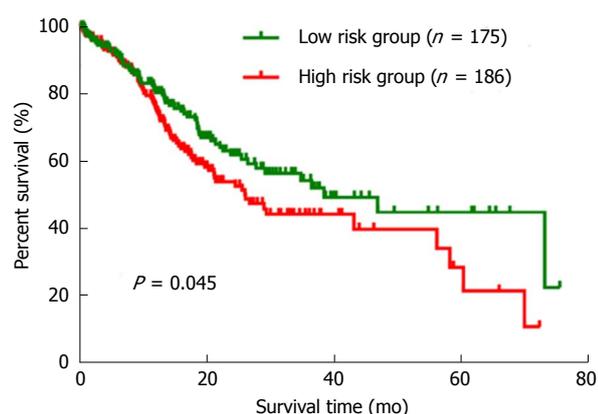

Figure 2 Hierarchical clustering analysis of the differentially expressed miRNAs between 20 pairs of gastric cancer and adjacent normal sample. Each row represents the expression of an miRNA and each column represents a sample: orange color for gastric cancer, blue for normal.

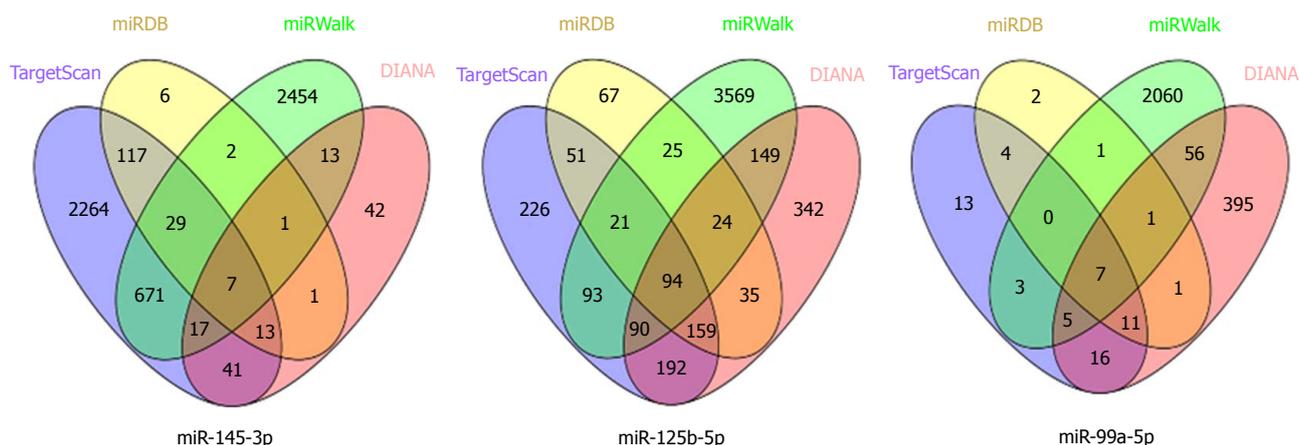

**Figure 3** Three differentially expressed miRNAs are negatively associated with overall survival in gastric cancer. A: Patients with a high level of miR-145-3p ( $n = 180$ ) had a poorer prognosis than those with a low level of miR-145-3p ( $n = 181$ ) ( $P = 0.0049$ ). B: Patients with a high level of miR-125b-5p ( $n = 180$ ) had a poorer prognosis than those with a low level of miR-125b-5p ( $n = 181$ ) ( $P = 0.0063$ ). C: Patients with a high level of miR-99a-5p ( $n = 180$ ) had a poorer prognosis than those with a low level of miR-99a-5p ( $n = 181$ ) ( $P = 0.047$ ).

**Figure 4** The Kaplan-Meier curve for the three-miRNA signature in gastric cancer. The three differentially expressed miRNAs were ranked by the median of expression and then scored for each gastric cancer patient in accordance with high or low-level expression. The low risk group ( $n = 175$ ) and high risk group ( $n = 186$ ) were defined by the total scores. Compared to the low risk group, patients in the high risk group had a poorer prognosis ( $P = 0.045$ ).

negatively associated with overall survival. Additionally, we constructed a three-miRNA signature to predict the prognosis of GC patients.

For decades, a large number of studies have reported that miRNAs can play oncogenic or tumor-suppressing roles in regulating cell biological behavior of cells<sup>[15-18]</sup>. At present, several miRNAs are known to be useful in the early diagnosis of cancers, including miR-21<sup>[19]</sup>, miR-486<sup>[20]</sup>, miR-24<sup>[21]</sup>, and miR-125a-5p<sup>[22]</sup>. In addition, miR-191<sup>[23]</sup>, miR-1908<sup>[24]</sup>, miR-200c<sup>[25]</sup>, and miR-217<sup>[26]</sup> were found to be potential prognostic indicators in cancer. However, these studies only used a single indicator or a limited number of patients for survival analysis. In this study, we identified DEMs by analyzing the array data from the GEO database and found that three highly expressed miRNAs (miR-145-3p, miR-125b-5p, and miR-99a-5p) may be potential prognostic indicators in GC. Kaplan-Meier and Log-rank test survival analysis indicated that the three-miRNA

**Figure 5** The consensus target genes of each differentially expressed miRNA. The target genes of the three miRNAs were predicted with four online tools (TargetScan, miRDB, miRWalk, and DIANA).

NA: Not available.

signature can be used to predict the prognosis of GC patients.

We then searched present publications online to compare and test our findings. Chang *et al.*<sup>[27]</sup> showed that miR-125b-5p was overexpressed in GC patients and promoted invasion and metastasis of GC by targeting *STARD13* and *NEU1*. It was also indicated that miR-125b-5p could be a potential biomarker for predicting

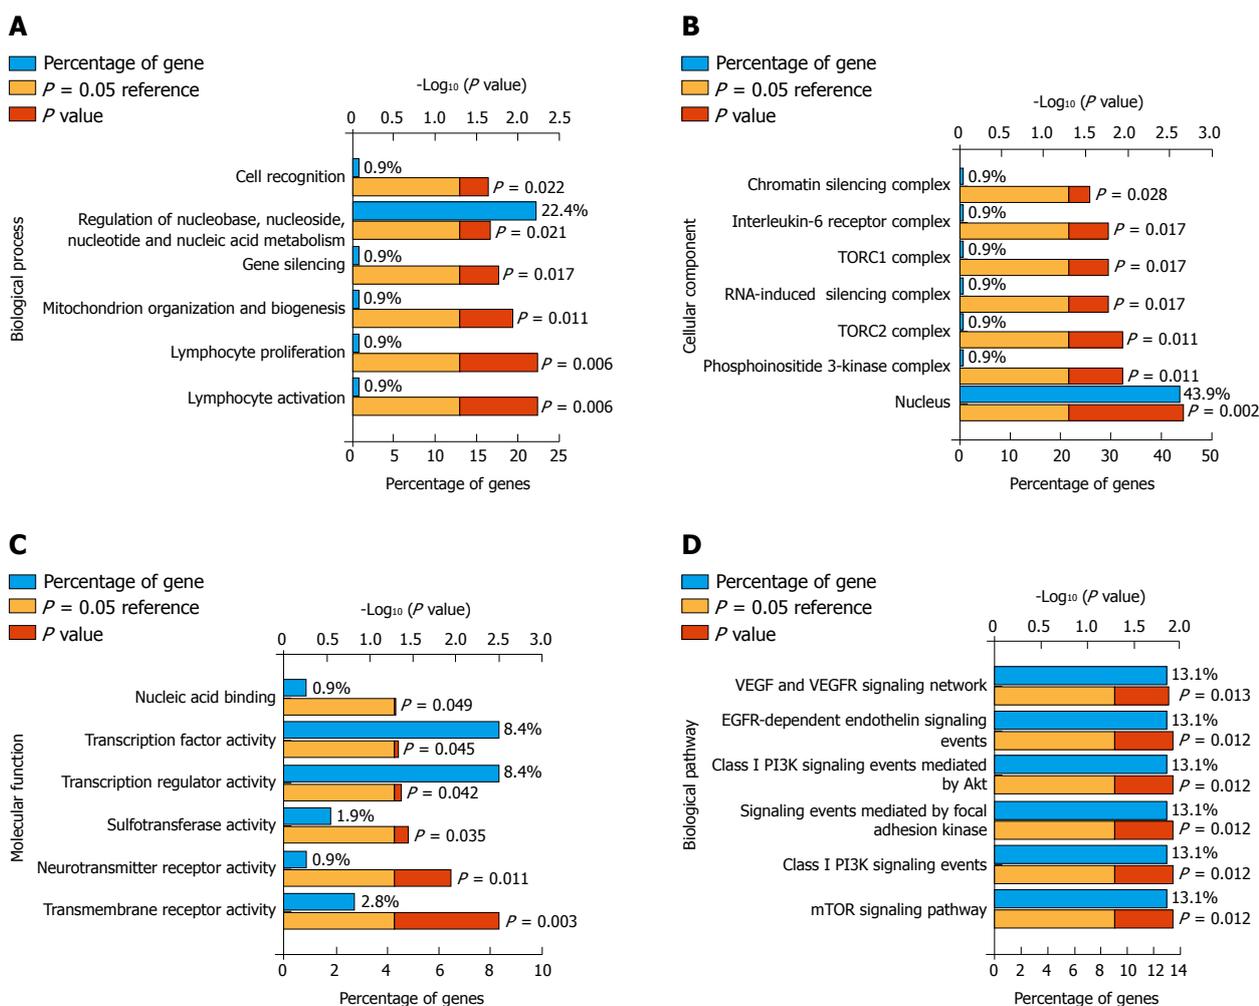

prognoses and clinical outcomes in patients with HER2-positive GC that receive trastuzumab treatment<sup>[28]</sup>. Wu *et al.*<sup>[29]</sup> found that miR-125b-5p promotes cell migration and invasion by targeting PPP1CA-Rb signal pathways and acts as an independent prognostic factor in GC. Furthermore, Zhang *et al.*<sup>[30]</sup> demonstrated that miR-99a-5p might function as a novel molecule to regulate cisplatin resistance by directly targeting the calpain small subunit 1 (CAPNS1)-associated pathway in GC. Interestingly, there are no studies describing relations between miR-145-3p and GC. However, in non-small cell lung cancer, miR-145-3p was found to inhibit cancer cell migration and invasion by targeting *PDK1* via the mTOR signaling pathway<sup>[31]</sup>. Moreover, miR-145-3p was also identified to be down-regulated in metastatic castration-resistant prostate cancer and target four molecules which can significantly predict survival in prostate cancer<sup>[32]</sup>. These results may suggest that miR-145-3p has a complicated effect in different cancers and, in future research, we will investigate the role of miR-145-3p in GC.

Dysregulated genes may participate in tumorigenesis and progression by aberrant signaling pathways. In this study, we predicted the target genes of the three miRNAs and performed gene functional enrichment analysis. The results showed that these target genes were associated with the process of gene silencing and cell recognition, as well as focal adhesion, EGFR, PI3K/Akt, and mTOR signaling pathways. Xu *et al.*<sup>[33]</sup> suggested that the EGFR-Akt signaling pathway regulates drug resistance in GC patients. The PI3K/Akt pathway was demonstrated to be associated with poor prognosis, tumor progression, and resistance to systematic therapy in many cancers including GC<sup>[34,35]</sup>. In addition, the PI3K/Akt/mTOR pathway is a key signaling pathway that is reported to be involved in GC<sup>[36]</sup>. Thus, the results of our functional enrichment analysis are in accordance with present studies.

Above all, we identified a three-miRNA signature for predicting the prognosis of patients with GC and

analyzed potential signaling pathways in the development and progression of GC. However, to determine the genesis and development mechanism of GC, more large-scale and systematic investigations are required.

## ARTICLE HIGHLIGHTS

### Research background

Increasing studies have reported that microRNAs (miRNAs) play an important role in the development and progression of cancers, including gastric cancer (GC). Furthermore, miRNAs can also act as accurate biomarkers in diagnosis and prognosis prediction. In this study, we found that a three-miRNA signature could be used for predicting the prognosis of GC patients and multiple miRNAs together acting as biomarkers may have a stronger reliability in survival prediction.

### Research motivation

The worldwide incidence and mortality rates of GC are fairly high. Most of GC patients have been in the advanced stage when diagnosed and endure a poor prognosis. Identifying accurate biomarkers in predicting prognosis of patients is an urgent issue to be solved, so that patients could have an individualized treatment and an improvement in prognosis.

### Research objectives

We aimed to identify multiple miRNAs for predicting the prognosis of patients with gastric cancer. In the present study, we found that a three-miRNA (miR-145-3p, miR-125b-5p, and miR-99a-5p) signature could be used for predicting the prognosis of patients with gastric cancer. This objective could be applied to clinical practice and have a guidance role in improving the prognosis of patients with gastric cancer.

### Research methods

We obtained the differentially expressed miRNAs by analyzing a microarray dataset from the Gene Expression Omnibus database with the limma package in R. The Kaplan-Meier method and log-rank test were used for describing the survival curve. The target genes of the three miRNAs (miR-145-3p, miR-125b-5p, and miR-99a-5p) were predicted with the online tools of TargetScan, miRDB, miRWalk, and DIANA. Venn plot was performed to obtain the common target genes from these four online tools. Enrichment analysis was conducted on the consensus genes using the FunRich tool.

### Research results

In the present study, we found that a three-miRNA (miR-145-3p, miR-125b-5p, and miR-99a-5p) signature could be used for predicting the prognosis of patients with gastric cancer. Multiple miRNAs together acting as prognosis-related biomarkers may have a stronger reliability and this finding could be useful in clinical treatment according to gastric cancer patients with different prognoses. However, the role of miR-145-3p in the tumorigenesis and progression of gastric cancer remains unclear. Thus, this problem remains to

be solved in our future study.

### Research conclusions

Our study identified that the three miRNAs (miR-145-3p, miR-125b-5p, and miR-99a-5p) were up-regulated in gastric cancer patients by analyzing a microarray dataset. Besides, the novel three-miRNA signature could be used for predicting the prognosis of patients with gastric cancer. Multiple miRNAs together acting as prognosis-related biomarkers may have a stronger reliability, so that our finding could be useful in clinical treatment according to gastric cancer patients with different prognoses.

### Research perspectives

This study provides us with a new insight that multiple miRNAs can be together used for predicting the prognosis of patients with gastric cancer. In order to further confirm the prognostic value of the three-miRNA signature, our future research may focus on exploring the relation between miR-145-3p and gastric cancer.
