Current evidence of drug-elution therapy for infrapopliteal arterial disease

Stavros Spiliopoulos, Nikiforos Vasiniotis Kamarinos, Elias Brountzos

Abstract

The advent of new and sophisticated endovascular devices such as the drug-eluting stents (DES) and the drug-coated balloons (DCB), both of which provide targeted drug delivery to the affected vessels, made possible to address the reparative cascade of arterial wall injury following balloon angioplasty that results in restenosis. DES were first used for the treatment of infrapopliteal lesions almost 20 years ago, while more recently, DCB technology is being investigated in order to improve outcomes of endovascular below-the-
