Premonitory urges located in the tongue for tic disorder: Two case reports and review of literature

Abstract

BACKGROUND: Premonitory urges was defined as the uncomfortable physical sensations of inner tension that can be relieved by producing movement responses. Nearly 70-90% patients with Tourette syndrome reported experiences of premonitory urges.

CASE SUMMARY: In this paper, we present two cases of young patients with Premonitory urges located in their tongue, which is very rare and easily misdiagnosed in clinical work. Both two young patients complained of an itchy tongue and cannot help biting their tongue. These two cases were worth reporting because it was rare that premonitory urges was the initial symptom and located in the tongue. The results indicated that premonitory urges seem to play an important role in the generation of tics.

CONCLUSION: Thus, premonitory urges may be the first process, and an essential part, of the formation of tics.

Keywords: premonitory urges, sensory tics, tic disorders, Tourette syndrome.

Core tip: These two cases were worth reporting because it was rare that premonitory urges was the initial symptom and located in the tongue. The results indicated that premonitory urges seem to play an important role in the generation of tics.

One important characteristic of tics and tic disorders is that they rarely occur by themselves. Tic disorders—particularly TS—have a high rate of comorbidity with other childhood disorders. The term comorbid is used to refer to a disease or disorder that occurs at the same time as another disorder.
