SPECIFIC COMMENTS TO AUTHORS

This study provides important information that could lead to improvement of a critical complication of hepatic transplantation. The methodology of the study, including the statistical methods, is appropriate. The presentation of the study can be improved. I

have the following suggestions for the authors: A. The last sentence of the Introduction appears to be incomplete. An added sentence stating that this study evaluated the effect of hepatic blood flow immediately after transplantation on the development of EAD and on the 30-day postoperative mortality would inform the readers of this report about the aims of this study. B. Both Table 1 and Table 2 contain the term "UCI time". Is "UCI" "ICU"? If yes, please correct. If not, please add and explain the term UCI in the Abbreviations. C. The subsection "Effects of liver blood flow in the 30-days patient survival" of the Results section states that 8 variables were found to be significantly associated with the 30 day survival by COX regression analysis. Table 3 shows the relevant statistics. Among these 8 variables, 3 including the needs for red cells, platelets and plasma did not achieve statistical significance as shown in Table 3. Please explain or correct this apparent discrepancy. D. Finally, the English of the report needs improvement, especially in the Results and Discussion sections. I will use the first paragraph of the Results as example: (a) "receptor" should be changed to "recipient" in two sentences. (b) The sentence immediately after the first "receptor" is unclear. (c) In the last sentence of the the paragraph, the word "differences" should be inserted between "Significant" and "between".

hepatic inflow needs to be further strengthened.No objective is mentioned in the introduction section 5 Methods. Inclusion of patients requiring urgent transplants and re transplants makes the study group heterogeneous. We know that sicker patients are more likely to develop EAD and so represents a possible bias. The surgical technique of transplantation is primary and re transplants should be elaborated. Did the study include only DBD or DCD donors as well? There is limited description on how the portal and arterial flow was measured. It should be elaborated further. How the flow meter was used. What was the role of doppler. If there was intra operative HAT or PVT, a redo anastomosis was performed and the flow measured again? 6 Results. Also give the range of MELD scores in transplant recipients. HAF was significantly lower in the group with EAD (227.74 ± 134.13 ml/min) when compared to the no-EAD group (279.67 ± 152.87 ml/min). What was the P value? Why a cut off of 180 was used? PVF was significantly lower in the group with EAD (1363.84 ± 602.06 ml/min) when compared to the no-EAD group (1606.73 ± 491.51 ml/min). Give P value and explain why a cut off of 1200 was used. 7 Discussion. How the OLTHOFF criteria could lead to false positives? Explain. The authors mention that if arterial buffer response was present on clamping of portal vein, strategies to reduce portal flow like splenectomy and splenic artery ligation were considered. This would in turn lead to reduction of portal flow under 1300. Whereas authors have shown that $PVF < 1200$ was an independent predictor of EAD. The two statements are contradictory and need clarification. Are the authors suggesting that low arterial flow is more detrimental than low portal flow? If so, it should be shown in results.

SPECIFIC COMMENTS TO AUTHORS

The authors describe an interesting study. The Manuscript is well written. The concept of intraoperatively control of the blood flow in the portal vein and HAT is, at least in the pediatric field, not new, but analyzing outcome based on flow in ml/min is a smart

approach. I wonder if the authors could add some variables to their analyses, which can have influence on the measured blood flow for example: - Size of spleen in the recipient - Portal flow of the recipient before transplant - Arterial blood pressure of recipient during reperfusion and intraoperative measurement of HAT blood flow - Hematocrit at time of intraoperative blood flow measurement One aspect of the method remained unclear for me. If the intraoperatively measured blood flow was very low, does the surgeon tried to improve the blood flow and if he was successful at this, how was this taken into account for the study analyses. Please add some information about the immunosuppressive protocol for your study patients.
