We present a rare case of esophageal tuberculosis causing odynophagia. Tuberculosis of the esophagus is a rare condition, even in countries with a high incidence of tuberculosis (TB) and studies estimate that it constitutes about 0.3% of gastrointestinal TB cases.

This is a case report of a rare form of tuberculosis in a patient presenting with dysphagia. Patient was subjected to upper gastrointestinal endoscopy, which revealed an ulcerative growth in the distal esophagus. Histopathology revealed esophageal tuberculosis. Patient was managed conservatively with Anti-Tuberculosis Treatment (ATT).

Abstract

BACKGROUND

Tuberculosis (TB) has a rare extrapulmonary manifestation known as esophageal tuberculosis, accounting for 0.2% of the total TB patients. Esophageal TB typically presents with dysphagia, with retrosternal pain or odynophagia, but generalized symptoms such as low-grade fever, decreased appetite and weight loss are also observed. Esophageal carcinoma and Crohn’s disease of the esophagus are important differential diagnoses with similar presentation.

CASE SUMMARY

We present a case of 25 years old male who presented with esophageal TB mimicking an esophageal carcinoma. Lab work-up, Mantoux test and chest X-ray were normal. Barium-swallow examination showed moderate dilatation of distal esophagus with a nodular and irregular mucosa. Computed tomography showed significant thickening of thoracic and distal esophagus with infiltration into the lesser omentum and large, centrally necrotic lymph nodes on gastro-hepatic ligament suggestive of a possible malignancy.

Discussion. Most **cases of esophageal tuberculosis** are secondary to direct extension from adjacent structures, such as mediastinal lymph nodes or pulmonary sites. **Primary esophageal tuberculosis** is even rarer [9]. **Esophagic** involvement by **tuberculosis** usually affects the middle third of the **esophagus** at the carina level [10].
