**Manuscript Type:** CASE REPORT

Effective administration of cranial drilling therapy in the treatment of fourth degree temporal, facial and upper limb burns at high altitude: a case report

## Abstract

### BACKGROUND

Fourth degree burns damage the full thickness of the skin and affect underlying tissues. Skin grafting after debridement is often used to cover the wounds of salvageable severe burns. The granulation wound can be formed by drilling the skull to the barrier layer to solve the problem of skull exposure. Low oxygen levels present at high altitudes aggravate ischemia and hypoxia which can negatively impact on wound healing. The impaired healing in such cases can be ameliorated by hyperbaric oxygen therapy.
