## SPECIFIC COMMENTS TO AUTHORS

• Title should be corrected (the current title reflex only one intervention - liver resection - while the cases of transarterial chemoembolization were also studied and compared). • Abstract summarizes and reflect the work described in the manuscript adequate. • Key words are relevant. • Background adequately describes the present status and significance of the study. • Selected methods for the review and meta-analysis are appropriate. • The main results lead to following: QOL is better after hepatectomy than after TACE. QOL is better after laparoscopic hepatectomy than after open hepatectomy. These results can be taken into consideration in planning interventions for hepatocellular carcinoma. • The provided discussion should be considered as satisfactory. It is constructed clearly and logically. • The provided figures and tables add light to the presented material. Beside the quality of figures should be improved. • The statistical methods represent one of the good choices taking into the account the aim and methodology of presented research. • The selected references response the requirement of World Journal of Gastroenterology. •

The manuscript style, language and grammar should be improved. Several sad mistakes were found, for example: "Mortality after hepatectomy has improved" should be changed as "Mortality after hepatectomy has decreased" etc. It is recommended to be checked by the native speaker. • Authors have prepared their manuscripts according to PRISMA 2009 Checklist - Evidence-Based Medicine, Systematic review, Meta-Analysis.

#### **SPECIFIC COMMENTS TO AUTHORS**

Authors submitted a meta-analysis reporting on QoL after liver resection. The paper could be interesting, especially considering success of (not so) new approaches, like laparoscopy. Some topics need to be assessed. The paper should assess “patients that have undergone liver resection”, therefore the analysis on hepatectomy vs TACE is off topic for different reasons. First of all because TACE is of course not a resection. Then TACE is used mainly for HCC (a selected subset of patients) and as Authors themselves state, patients candidate to TACE are quite different to patients treated with liver resection. The main limit of the paper is heterogeneity. Authors analysed 10 papers covering too large a span of time (2001-2019). Then the papers analysed reports of different disease. 4 papers reports only on HCC (one of which on even a more selected group of patients HCC+ thrombi). 2 papers reports on on hemangiomas, 1 on “miscellaneous” benign lesions. The analysis that could have been more interesting and current, lap vs open resections is conducted on papers on benign lesions. Some minor aspect to assess: Abstract conclusion: it is no no conclusion, just underline the limit of the analysis Introduction: statement on “hepatectomy” refer mainly on paper regarding HCC [2,3,4] Discussion: The FACT-Hep paragraph: “Our results indicate that HCC patients QoL... The studies included in this analysis included patients with severe symptoms ... [27,29]. The cited papers refer on Hemangioma, not HCC. In conclusion, the meta analysis could have been interesting but the small number and heterogeneity of the articles available for the analysis make the paper of limited interest.
