**ABOUT COVER**

Editorial Board Member of *World Journal of Clinical Cases*, Farooq Shahzad, FACS, MBBS, MS, Assistant Professor, Plastic Surgery Service, Department of Surgery, Memorial Sloan-Kettering Cancer Center, New York, NY 10065, United States. fooqs@hotmail.com

**AIMS AND SCOPE**

The primary aim of *World Journal of Clinical Cases* (WJCC, *World J Clin Cases*) is to provide scholars and readers from various fields of clinical medicine with a platform to publish high-quality clinical research articles and communicate their research findings online.

WJCC mainly publishes articles reporting research results and findings obtained in the field of clinical medicine and covering a wide range of topics, including case control studies, retrospective cohort studies, retrospective studies, clinical trials studies, observational studies, prospective studies, randomized controlled trials, randomized clinical trials, systematic reviews, meta-analysis, and case reports.

**INDEXING/ABSTRACTING**

The WJCC is now abstracted and indexed in Science Citation Index Expanded (SCIE, also known as SciSearch®), Journal Citation Reports/Science Edition, Current Contents®/Clinical Medicine, PubMed, PubMed Central, Scopus, Reference Citation Analysis, China National Knowledge Infrastructure, China Science and Technology Journal Database, and Superstar Journals Database. The 2022 Edition of Journal Citation Reports® cites the 2021 impact factor (IF) for WJCC as 1.534; IF without journal self cites: 1.491; 5-year IF: 1.599; Journal Citation Indicator: 0.28; Ranking: 135 among 172 journals in medicine, general and internal; and Quartile category: Q4. The WJCC's CiteScore for 2021 is 1.2 and Scopus CiteScore rank 2021: General Medicine is 443/826.

## Abstract

### BACKGROUND

Allergic bronchopulmonary aspergillosis (ABPA) is an immune-related pulmonary disease caused by sensitization of airway by *Aspergillus fumigatus*. The disease manifests as bronchial asthma and recurring pulmonary shadows, which may be associated with bronchiectasis. The diagnosis of ABPA mainly depends on serological, immunological, and imaging findings. Pathological examination is not necessary but may be required in atypical cases to exclude pulmonary tuberculosis, tumor, and other diseases through lung biopsy.

### CASE SUMMARY

An 18-year-old man presented with recurrent wheezing, cough, and peripheral blood eosinophilia. Chest computed tomography showed pulmonary infiltration. There was a significant increase in eosinophils in bronchoalveolar lavage fluid. There was no history of residing in a parasite-endemic area or any evidence of parasitic infection. Pathologic examination of bronchoalveolar lavage fluid excluded fungal and mycobacterial infections. The patient was receiving medication for comorbid diseases, but there was no temporal correlation between medication use and clinical manifestations, which excluded drug-induced etiology. Histopathological examination of lung biopsy specimen showed no signs of eosinophilic granulomatosis with polyangiitis, IgG4-related diseases, or tumors. The diagnosis of ABPA was considered based on the history of asthma and the significant increase in serum *Aspergillus fumigatus*-specific immunoglobulin (Ig)E. Eosinophil-related diseases were excluded through pathological

biopsy, which showed typical pathological manifestations of ABPA.

### CONCLUSION

The possibility of ABPA should be considered in patients with poorly controlled asthma, especially those with eosinophilia, lung infiltration shadows, or bronchiectasis. Screening for serum IgE, *Aspergillus fumigatus*-specific IgE and IgG, and alveolar lavage can help avoid misdiagnosis.

**Key Words:** Allergic bronchopulmonary aspergillosis; Asthma; *Aspergillus*; Case report

©The Author(s) 2023. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core Tip:** Clinically, allergic bronchopulmonary aspergillosis should be considered for patients with poorly controlled asthma, especially those with elevated eosinophils, pulmonary infiltrates, or bronchiectasis. Serum total immunoglobulin (Ig)E (IgE), *Aspergillus fumigatus*-specific antibody IgE and IgG detection can help confirm the diagnosis.

## INTRODUCTION

Allergic bronchopulmonary aspergillosis (ABPA) is an immune-related pulmonary disease caused by airway sensitization by *Aspergillus fumigatus*, manifesting as bronchial asthma and recurring pulmonary shadows which may be associated with bronchiectasis. The disease is relatively rare and is often misdiagnosed or missed clinically. Early diagnosis and timely treatment with systemic glucocorticoids can control the disease and prevent irreversible lung damage. The estimated prevalence of ABPA in asthma patients worldwide is approximately 2.5%[1]. In the general population, secretory immunoglobulin (Ig)E in the bronchi or IgG in serum normally clears the inhaled *Aspergillus* spores; however, in patients with asthma or cystic fibrosis, the inhaled *Aspergillus* spores can colonize the airways, inducing immunity in the bronchi and lung interstitium. Inflammatory reactions, mainly type I and type III hypersensitivity reactions, promote the production of IgE, IgG, and IgA. This inflammatory response is mainly triggered due to the activation of eosinophils mediated by T helper 2 (Th2) cells[2]. The activation of this inflammatory response is mainly due to the activation of eosinophils mediated by Th2 cells[3]. The typical manifestations of ABPA are poorly controlled asthma or repeated pulmonary infiltrates with or without bronchiectasis. Up to one-third of all cases in developing countries are misdiagnosed as pulmonary tuberculosis[3]. In this article, we report a case of ABPA and review the clinical features of ABPA including clinical manifestations and serological, imaging, and pathological findings, which may help improve the diagnosis and treatment of this disease.

## CASE PRESENTATION

### Chief complaints

An 18-year-old man was admitted to the hospital on February 5, 2021 with a history of intermittent wheezing for the last 15 years, which was aggravated for the last 9 d.

### History of present illness

Fifteen years ago, the patient was diagnosed with bronchial asthma. He regularly received salmeterol and ficasone inhalation (50 µg/100 µg or 50 µg/2500 µg, 1 inhalation bid), but acute exacerbations usually occurred 1-2 times every year, typically between the months of October and December. Nine days before admission, the patient developed wheeze but had no fever. His white blood cell count was  $10.56 \times 10^9/L$ , neutrophil percentage was 45.3%, and eosinophil percentage was 17.6%. He was treated with an antibiotic (moxifloxacin) for 3 d, but there was no significant improvement in symptoms. Two days before admission, he had cough with a small amount of white colored sputum. Chest computed tomography (CT) showed consolidation in the anterior basal segment of the right lower lobe, and there

were multiple small nodules with fuzzy margins around the periphery, some of which had merged into small patches of consolidation (Figure 1). Therefore, he was hospitalized for further evaluation and treatment.

### History of past illness

The patient's past history included congenital hip dislocation since childhood and developmental deformity of the lower extremities, due to which he was relying on a wheelchair for mobility. The patient was diagnosed with neurogenic bladder 6 years ago due to dysuria and obstructive renal insufficiency due to urinary retention. Cystostomy was performed 5 years ago. Hypertension was diagnosed 5 years ago (systolic blood pressure up to 160 mmHg). His blood pressure was controlled below 130/90 mmHg after treatment with oral fosinopril (10 mg, qd). Scoliosis deformity was discovered 4 years ago. He was also prescribed oral sertraline 50 mg once a night for treatment of depression 4 years ago. Two years ago, he was prescribed oral omeprazole for treatment of reflux esophagitis.

### Personal and family history

There was a positive family history of bronchial asthma (the patient's mother and grandmother were both affected).

### Physical examination

Physical examination on admission revealed the following: Body temperature, 36.7 °C; pulse, 104 beats/min; respiratory rate, 18 beats/min; blood pressure 131/87 mmHg (1 mmHg = 0.133 kPa). The patient was conscious and had no signs of cyanosis. No dry or wet rales were heard in either lung. Cardiovascular and abdominal examinations were unremarkable.

### Laboratory examinations

Laboratory tests after admission revealed the following: White blood cell count,  $11.75 \times 10^9/L$ ; hemoglobin 159 g/L; platelet count,  $201 \times 10^9/L$ ; neutrophil percentage 41.7% (absolute value  $4.9 \times 10^9/L$ ); eosinophil percentage 24% 6% (absolute value  $2.89 \times 10^9/L$ ); serum procalcitonin 0.056 ng/mL; C-reactive protein 1.43 mg/dL; T-SPOT, G test, GM test, *Mycoplasma pneumoniae* antibody, and *Chlamydia pneumoniae* antibody were all negative; antineutrophil cytoplasmic antibodies and antinuclear antibody profiles were also negative; allergen total IgE > 5000 KU/L; *Aspergillus fumigatus* ( $m^3$ ) 66.4 (grade 5) KU/L; *Aspergillus* antibody IgG 276.2 AU/mL (reference value < 80) (Table 1).

### Imaging examinations

To further clarify the nature of the lung lesions, bronchoalveolar lavage fluid was examined. On cell count in the bronchoalveolar lavage fluid (Table 1), the proportion of eosinophils was 35%. Further ultrasound-guided percutaneous lung biopsy was performed; histopathological findings (Figure 2) were presence of alveolar structures, mild widening of alveolar septa, and infiltration of a large number of eosinophils and a small amount of scattered lymphoplasmacytic cells in the alveolar septum; interstitium. small amount of eosinophilic exudation was seen in some alveolar spaces, with no signs of necrosis, typical granulomas, or vasculitis. Based on the history of asthma, peripheral blood eosinophilia, significantly increased serum allergen total IgE, and positive *Aspergillus fumigatus*-specific IgE and IgG, a diagnosis of ABPA was established. After 1 mo of prednisone treatment, a routine blood test showed that the white blood cell count was  $9.13 \times 10^9/L$ , and the eosinophil percentage was 0.4% (absolute value  $0.04 \times 10^9/L$ ). Chest CT (Figure 3) showed resorption of shadow in the right lower lobe; only fibrous cords were seen.

## FINAL DIAGNOSIS

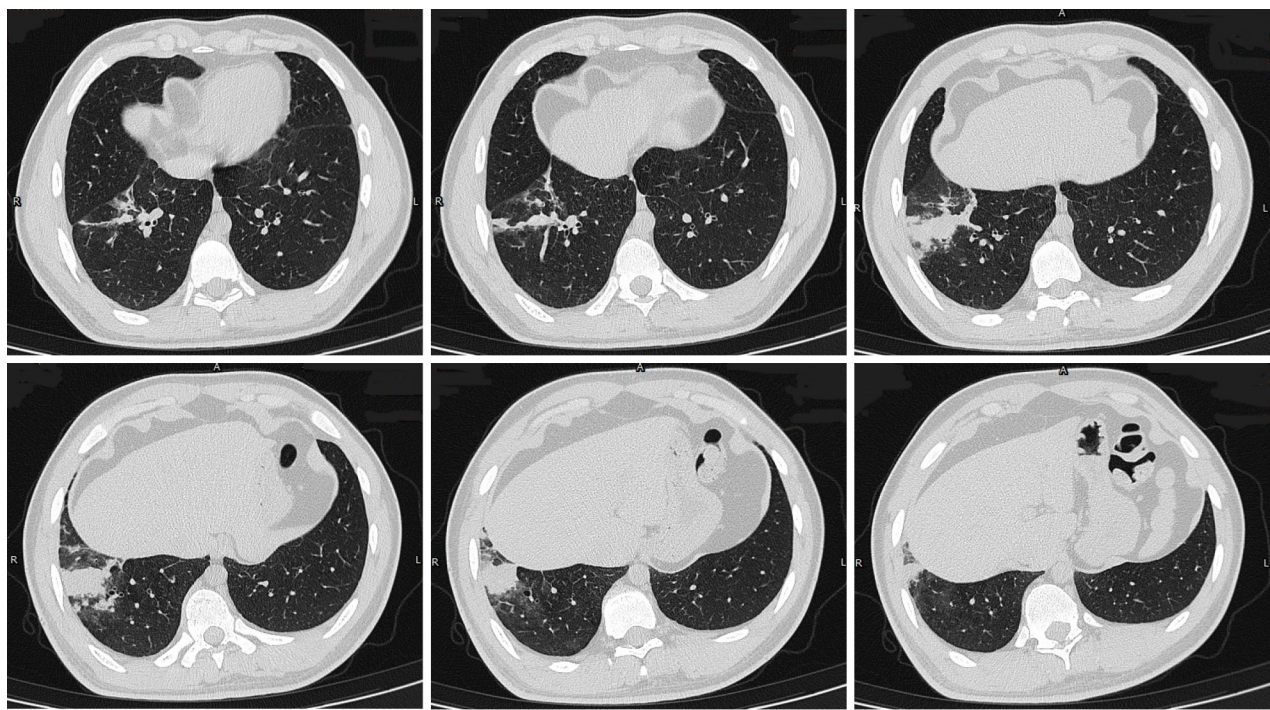

Based on the history of asthma, peripheral blood eosinophilia, significantly increased serum allergen total IgE, and positive *Aspergillus fumigatus*-specific IgE and IgG, a diagnosis of ABPA was established.

## TREATMENT

The patient was prescribed prednisone 20 mg qd orally for 2 mo, which was gradually tapered to 10 mg qd for 6 mo. In addition, he was prescribed antifungal treatment with itraconazole 0.2 g bid for 6 mo to reduce fungal colonization in the airway and the persistent inflammatory reaction caused by fungal antigen stimulation.

Table 1 Laboratory indices

	Test results	Reference range
Peripheral blood eosinophil percentage	28.7%	(0.4-8)%
Absolute value	$2.56 \times 10^9/L$	$(0.02-0.52) \times 10^9/L$
Serum allergen total IgE	> 5000 KU/L	0-60
Serum <i>Aspergillus fumigatus</i> (m3) specific IgE	66.4 (5 grade) KU/L	0-0.35
Serum <i>Aspergillus fumigatus</i> specific IgG	276.2 AU/mL	< 80
Bronchoalveolar lavage fluid total cells	$5.8 \times 10^5/mL$	
Macrophages	40%	> 85%
Neutrophils	2%	≤ 3%
Lymphocytes	23%	(10-15)%
Eosinophils	35%	≤ 1%

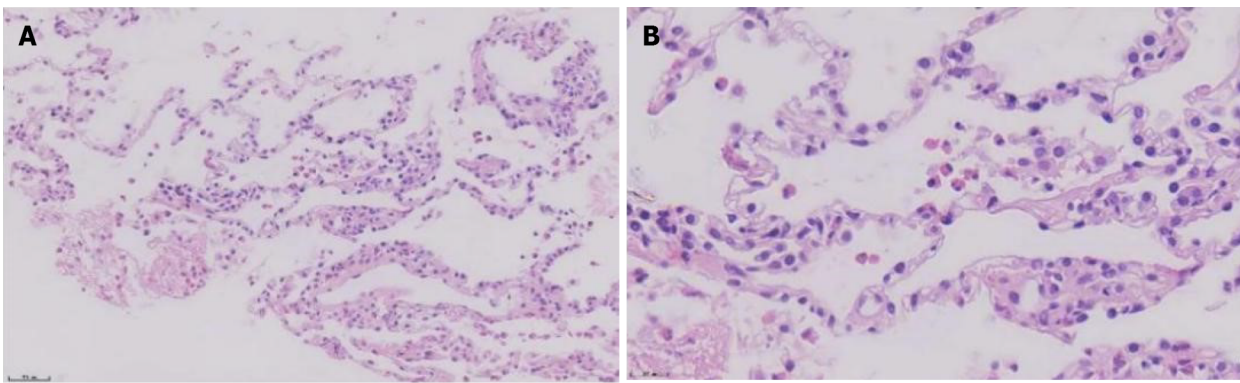

Figure 1 Chest computed tomography images (February 3, 2021) showing consolidation in the anterior basal segment of the right lower lobe, with multiple small nodules surrounded by blurred margins, some of which merged into small patchy consolidations.

OUTCOME AND FOLLOW-UP

After 1 mo of prednisone treatment, the patient’s white blood cell count was  $9.13 \times 10^9/L$ , and the eosinophil percentage was 0.4% (absolute value  $0.04 \times 10^9/L$ ). Chest CT (Figure 2) showed resorption of shadow in the right lower lobe; only fibrous cords were seen and the adjacent bronchi were stretched and dilated.

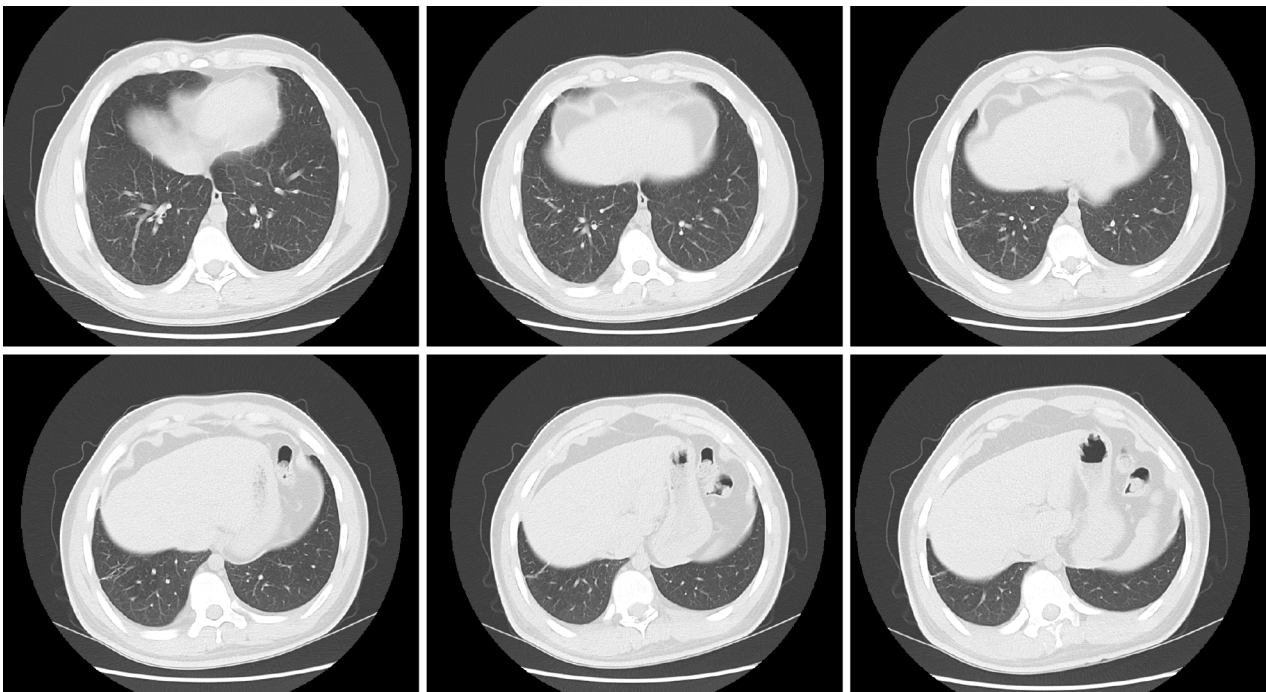

DISCUSSION

The main manifestations of this patient were recurrent wheezing and cough, eosinophilia, pulmonary infiltration shadow, and significantly increased eosinophils in bronchoalveolar lavage fluid. We considered increased eosinophils in bronchoalveolar lavage fluid as the breakthrough point and made differential diagnoses according to pulmonary eosinophilia.

**Figure 2 Hematoxylin-eosin-stained sections of lung tissue.** A: Magnification  $\times 20$ ; B: Magnification  $\times 40$ . The alveolar structure can be identified, the alveolar septum is slightly widened, and there are many eosinophils and a small amount of scattered lymphoplasmacytic infiltration in the alveolar septum and interstitium. A small amount of eosinophilic exudation can be seen in some alveolar spaces with no signs of necrosis. No typical granulomas or vasculitis is observed.

**Figure 3 Repeat chest computed tomography performed after 4 wk of glucocorticoid treatment showing resorption of the shadow in the right lower lobe; only a fibrous cord shadow is seen, and the adjacent bronchus is stretched and dilated.**

The term pulmonary eosinophilia refers to a group of heterogeneous diseases with common characteristics of abnormal increase in eosinophils in the lung airway and lung parenchyma. The characteristics include: (1) Peripheral blood eosinophilia (absolute eosinophil count  $\geq 500/\mu\text{L}$ ) with abnormal pulmonary imaging examination; (2) increased eosinophils in the bronchoalveolar lavage fluid ( $> 10\%$ ); and (3) presence of eosinophils in lung tissue confirmed by bronchopulmonary biopsy or open chest lung biopsy[1]. Pulmonary eosinophilia is classified into secondary and idiopathic. Secondary causes include infectious diseases (including parasitic, fungal, and mycobacterial infections), allergic diseases (related to ABPA, drugs, or toxicants), connective tissue disorders (eosinophilic granulomatosis with polyangiitis, IgG4-related diseases, *etc.*), malignancies (lymphoma, leukemia, solid tumors, *etc.*), and other diseases (bronchial central granulomatosis, interstitial lung disease, lung transplantation, hematopoietic stem cell transplantation, secondary to radiotherapy, *etc.*). Idiopathic pulmonary eosinophilia includes acute eosinophilic pneumonia (AEP), chronic eosinophilic pneumonia (CEP), and idiopathic hypereosinophilic syndrome (IHES).

Our patient had no history of residing in a parasite endemic area or consumption of raw meat, fish, shrimp, or crab, and there was no evidence of parasitic infection. Pathologic examination of bronchoalveolar lavage fluid excluded fungal and mycobacterial infections. The patient was receiving medication

for hypertension, hyperuricemia, depression, and gastroesophageal reflux disease; however, there was no temporal correlation between the medication and the patient's symptoms, eosinophilia, or pulmonary imaging changes. Therefore, any drug-induced etiology was not considered. Pathological examination of lung tissue revealed no signs of eosinophilic granulomatosis with polyangiitis, IgG4-related diseases, or tumors. The diagnosis of ABPA was considered based on the combination of history of asthma and significant increase of serum *Aspergillus fumigatus* IgE.

Elevated serum IgE was another feature of this patient. Serum IgE level can be elevated in many conditions, such as infectious diseases, atopic diseases, immunodeficiencies, inflammatory diseases, neoplasms, and drug-induced conditions; however, significantly elevated serum IgE (> 2000 KU/L or even 5000 KU/L) is seen in ABPA, IgE type multiple myeloma, and hyperimmunoglobulin E syndrome (HIES). IgE type multiple myeloma is extremely rare. Similar to other types of multiple myeloma, the clinical manifestations of IgE type multiple myeloma are anemia, renal dysfunction, hypercalcemia, and bone damage. Bone damage in patients with IgE type multiple myeloma manifests as osteoporosis, osteolytic damage, osteosclerosis, and pathological fracture[4], while osteolytic damage is more common in other types of multiple myeloma. HIES is a rare, primary immunodeficiency distinguished by the clinical triad of atopic dermatitis, recurrent staphylococcal skin infections, and recurrent pulmonary infections. Patients with HIES have characteristic facial features (facial asymmetry, prominent forehead, deep-set eyes, broad nasal bridge, and wide fleshy nasal tip) that appear in early adolescence or late childhood[5]. Our patient had no such symptoms, due to which IgE type multiple myeloma and HIES were excluded.

The diagnosis of ABPA is primarily based on serological, immunological, and imaging findings. Pathological examination is not necessary for diagnosis but may be required in atypical cases to exclude pulmonary tuberculosis, tumor, or other diseases through lung biopsy.

The main therapeutic goal in ABPA is to control asthma, reduce acute exacerbations, and prevent irreversible lung damage such as bronchiectasis and pulmonary fibrosis. The main therapeutic methods include systemic glucocorticoid therapy to suppress immune response, and use of antifungal drugs to reduce the colonization of respiratory tract[3]. At present, there is no clear consensus on the use of antifungal drugs in patients with ABPA, and these are recommended for patients with hormone dependence and relapse after discontinuation of hormone therapy. In addition, studies have also shown that omazumab (a humanized anti IgE monoclonal antibody) can reduce the serum IgE level of patients, the risk of acute exacerbation, and hormone dosage[6]. In terms of treatment follow-up, serum IgE is an important follow-up parameter apart from clinical symptoms and pulmonary imaging. The decrease in serum IgE indicates the effectiveness of treatment. Reducing the IgE to the normal range is often challenging in ABPA patients. Therefore, the goal of treatment is to reduce the IgE level by 35%-50%. In most cases, clinical and imaging improvements will be achieved. There are many published case reports of ABPA. However, there is a paucity of ABPA case reports describing the histopathological findings of lung biopsy. Thus, the present study presents the typical pathological manifestations of ABPA to readers.

## CONCLUSION

In clinical practice, for patients with poorly controlled asthma, especially those with elevated eosinophils, lung infiltration shadows, or bronchiectasis, the possibility of ABPA should be considered. Screening of serum IgE, *Aspergillus fumigatus*-specific IgE and IgG, and alveolar lavage should be performed to avoid missed diagnosis and misdiagnosis. Serum total IgE and *Aspergillus fumigatus*-specific IgE and IgG detection can help confirm the diagnosis.
