**ABOUT COVER**

Editorial Board Member of *World Journal of Gastrointestinal Oncology*, Zhi-Fei Cao, MD, PhD, Assistant Professor, Research Assistant Professor, Department of Pathology, The Second Affiliated Hospital of Soochow University, Suzhou 215004, Jiangsu Province, China. [hunancao@163.com](mailto:hunancao@163.com)

**AIMS AND SCOPE**

The primary aim of *World Journal of Gastrointestinal Oncology* (*WJGO*, *World J Gastrointest Oncol*) is to provide scholars and readers from various fields of gastrointestinal oncology with a platform to publish high-quality basic and clinical research articles and communicate their research findings online.

*WJGO* mainly publishes articles reporting research results and findings obtained in the field of gastrointestinal oncology and covering a wide range of topics including liver cell adenoma, gastric neoplasms, appendiceal neoplasms, biliary tract neoplasms, hepatocellular carcinoma, pancreatic carcinoma, cecal neoplasms, colonic neoplasms, colorectal neoplasms, duodenal neoplasms, esophageal neoplasms, gallbladder neoplasms, *etc.*

**INDEXING/ABSTRACTING**

The *WJGO* is now abstracted and indexed in PubMed, PubMed Central, Science Citation Index Expanded (SCIE, also known as SciSearch®), Journal Citation Reports/Science Edition, Scopus, Reference Citation Analysis, China National Knowledge Infrastructure, China Science and Technology Journal Database, and Superstar Journals Database. The 2023 edition of Journal Citation Reports® cites the 2022 impact factor (IF) for *WJGO* as 3.0; IF without journal self cites: 2.9; 5-year IF: 3.0; Journal Citation Indicator: 0.49; Ranking: 157 among 241 journals in oncology; Quartile category: Q3; Ranking: 58 among 93 journals in gastroenterology and hepatology; and Quartile category: Q3. The *WJGO*'s CiteScore for 2022 is 4.1 and Scopus CiteScore rank 2022: Gastroenterology is 71/149; Oncology is 197/366.

## Abstract

### BACKGROUND

Although the current conventional treatment strategies for esophageal carcinoma (EC) have been proven effective, they are often accompanied by serious adverse events. Therefore, it is still necessary to continue to explore new therapeutic strategies for EC to improve the clinical outcome of patients.

### AIM

To elucidate the clinical efficacy of concurrent chemoradiotherapy (CCRT) with thalidomide (THAL) and S-1 (tegafur, gimeracil, and oteracil potassium capsules) in the treatment of EC as well as its influence on serum tumor markers (STMs).

### METHODS

First, 62 patients with EC treated at the Zibo 148 Hospital between November 2019 and November 2022 were selected and grouped according to the received treatment. Among these, 30 patients undergoing CCRT with cis-platinum and 5-fluorouracil were assigned to the control group (Con), and 32 patients receiving CCRT with THAL and S-1 were assigned to the research group (Res). Second, inter-group comparisons were carried out with respect to curative efficacy, incidence of drug toxicities, STMs [carbohydrate antigen 125 (CA125) and macrophage inflammatory protein-3 $\alpha$  (MIP-3 $\alpha$ )], angiogenesis-related indicators [vascular endothelial growth factor (VEGF); VEGF receptor-1 (VEGFR-1); basic fibroblast growth factor (bFGF); angiogenin-2 (Ang-2)], and quality of life (QoL) [QoL core 30 (QLQ-C30)] after one month of treatment.

### RESULTS

The analysis showed no statistical difference in the overall response rate and disease control rate between the two patient cohorts; however, the incidences of grade I-II myelosuppression and gastrointestinal reactions were significantly lower in the Res than in the Con. Besides, the post-treatment CA125, MIP-3 $\alpha$ , VEGF, VEGFR-1, bFGF, and Ang-2 Levels in the Res were markedly lower

compared with the pre-treatment levels and the corresponding post-treatment levels in the Con. Furthermore, more evident improvements in QLQ-C30 scores from the dimensions of physical, role, emotional, and social functions were determined in the Res.

## CONCLUSION

The above results demonstrate the effectiveness of THAL + S-1 CCRT for EC, which contributes to mild side effects and significant reduction of CA125, MIP-3 $\alpha$ , VEGF, VEGFR-1, bFGF, and Ang-2 Levels, thus inhibiting tumors from malignant progression and enhancing patients' QoL.

**Key Words:** Thalidomide; Concurrent chemoradiotherapy; Esophageal carcinoma; Therapeutic effect; Serum tumor markers

**Core Tip:** Esophageal carcinoma (EC) is a common and fatal digestive tract tumor, and the current therapeutic methods such as surgical resection, radiotherapy and chemotherapy have limited effects and are accompanied by relatively serious adverse events. Therefore, clinical exploration of new treatment strategies for esophageal cancer should be continued to optimize the management of EC patients.

## INTRODUCTION

Esophageal carcinoma (EC) is a common fatal gastrointestinal (GI) tumor with a five-year survival rate of only 15%-25%. It is characterized by high malignancy, invasiveness, and easy metastasis[1]. According to global statistics, EC is broadly pathologically classified into esophageal squamous cell carcinoma and esophageal adenocarcinoma; the former is primarily distributed in Southeast Asia and Africa and the latter in Europe and North America[2,3]. Onco-pathologically, EC is shown to be associated with the abnormal proliferation of esophageal epithelial cells that induces invasive cancer or invasive adenocarcinoma; meanwhile, the etiology is related to factors such as esophageal mucosa contact with carcinogens and mechanical damage[4,5]. Moreover, the disease is mainly presented clinically as dysphagia and unexpected weight loss but usually with no specific early symptoms[6]. At the present stage, EC is mainly treated with surgical resection, radiotherapy, and chemotherapy. Despite the confirmed effectiveness of these conventional treatments, they are accompanied by serious adverse events, resulting in unsatisfactory clinical outcomes[7]. Therefore, there is an urgent need to explore new strategies for treating EC and optimizing the treatment options for patients with EC; this can be of great value for improving treatment efficacy as well as patient prognosis and symptoms.

Thalidomide (THAL), which was originally used as a sedative for the relief of vomiting and nausea during pregnancy, has been used to treat solid tumors because of its anti-angiogenesis effects[8]. Its anti-tumor mechanism is reported to be linked to the regulation of the secretion of vascular endothelial growth factor (VEGF) and basic fibroblast growth factor (bFGF)[9]. Another molecular study shows that THAL exerts immunomodulatory actions by altering the expression of tumor necrosis factor receptor superfamilies in T cell subsets[10]. The fluorouracil drug S-1 consists of tegafur, gimeracil, and oteracil potassium. It can be used to treat gastric, pancreatic, gallbladder, colorectal, and esophageal cancers[11,12] and has been shown to not only exert better anticancer performance than 5-fluorouracil (5-FU) but also reduce cancer cells' resistance to chemotherapy[13]. In the analysis by Wang *et al*[14], definitive concurrent chemoradiotherapy (CCRT) with S-1 and cisplatin significantly improved the survival outcomes of older adults ( $\geq 60$  years old) with EC.

The present study attempts to analyze the effectiveness of CCRT with THAL + S-1 for EC and its influence on serum tumor markers (STMs) in order to provide a new feasible scheme for improving the survival outcome of patients with EC.

## MATERIALS AND METHODS

### Patient information

The study population comprised 62 patients with EC treated at the Zibo 148 Hospital between November 2019 and November 2022. The patients were grouped according to the received treatment. A total of 30 patients undergoing CCRT with cis-platinum (DDP) and 5-FU were assigned to the control group (Con), and 32 patients receiving CCRT with THAL and S-1 were assigned to the research group (Res). The Con consisted of 17 males and 13 females with a mean age of  $61.03 \pm 6.91$  years, and the Res consisted of 19 males and 13 females with a mean age of  $61.44 \pm 10.61$  years. The present study is retrospective.

### Criteria for patient enrollment and exclusion

**Inclusion criteria:** (1) Patients gastroscopically and pathologically diagnosed with EC and meeting the American Joint Committee on Cancer clinical staging criteria for EC; (2) patients with a life expectancy of three or more months; (3) patients with a Karnovsky Performance Scale score of  $\geq 70$  points; (4) patients capable of eating semi-liquid food; and (5) patients with normal hepatorenal function and blood routines.

**Exclusion criteria:** (1) Patients with an intolerance to the treatment scheme of the present study; (2) patients with other malignancies; (3) patients with hepatic fibrosis, (4) patients with renal fibrosis and other systemic fibrosis; (5) patients undergoing chemotherapy or other adjuvant treatment programs; and (6) patients with distant metastasis of the tumor.

### Methods

All patients received three-dimensional intensity modulated radiation therapy. Gross tumor volume and organs at risk were delineated according to the pathology and imaging findings, and treatment schemes were specified based on patients' conditions. The prescribed dose was 56–70 Gy, with a single dose of 2 Gy administered five times a week for four weeks. Of these, 95% of the planned target area was irradiated with a prescription dose of at least 100% for the whole lung, no more than 25%–30% for V20, and no more than 18% for V30; the upper limits were set at 30 Gy and 45 Gy for the heart and the spinal cord, respectively.

The Con was treated with CCRT using DDP + FU. Cisplatin 20 mg/(m<sup>2</sup>·d) and 5-FU 500 mg/(m<sup>2</sup>·d) were given intravenously for 5 consecutive days; patients received two cycles of CCRT, which were performed at week 1 and week 4 of radiotherapy, respectively.

The Res received CCRT using THAL + S-1. Patients were given S-1 capsules, 40 mg/time, twice a day from day 1 to day 14; this was repeated every 21 days simultaneously with radiotherapy. The THAL was administered at a dose of 100 mg/d before bedtime in the first week and gradually increased to 200 mg/d in the second week until the end of radiotherapy. Patients in both groups were given symptomatic treatments, such as antiemesis, stomach protection, and nutritional support during chemotherapy, with their blood routines and hepatorenal function monitored weekly and biweekly, respectively.

### Outcome measures

**Short-term efficacy:** The clinical efficacy, which was evaluated with reference to the Response Evaluation Criteria in Solid Tumors, was determined as complete response (CR; the tumor disappeared completely, with smooth margins shown by the barium meal test, smooth passage of the barium agent, slightly rigid tube wall, no narrowing or slight narrowing of the lumen, and basically recovered or thickened mucosa), partial response (PR; most of the lesions disappeared without obvious distortion, angulation, or extraluminal ulcer; the barium passed smoothly, but the edges were not smooth, with small filling defects or niches, or the lumen was obviously narrowed, although the edges were smooth), stable disease (SD; the lesion had residual or no obvious improvement at the end of radiotherapy, with obvious filling defects or niches), or progressive disease (worsened niche or stenosis). The overall response rate (ORR) is the sum of patients with CR and patients with PR as a percentage of the total number of cases. The disease control rate (DCR) is the sum of the percentages of CR, PR, and SD. The short-term efficacy was evaluated after radiotherapy in both groups.

**Incidence of drug toxicities:** The adverse reactions of anticancer drugs were classified into grades I–II or III–IV according to the WHO classification of adverse drug reactions, and the number of cases of myelosuppression (MS), GI reactions, and radiation esophagitis (RE) as well as the percentages of the corresponding side effect grades were recorded.

**Serum tumor markers and angiogenesis-related indicators:** Before and after treatment, 5 mL of venous blood was collected on an empty stomach during the morning hours and sent to the laboratory for examination after centrifugation. The levels of carbohydrate antigen 125 (CA125), macrophage inflammatory protein-3 $\alpha$  (MIP-3 $\alpha$ ), VEGF, VEGF receptor-1 (VEGFR-1), bFGF, and angiogenin-2 (Ang-2) were determined by the enzyme-linked immunosorbent assay (ELISA).

**Quality of life (QoL):** Patients' QoL was assessed and compared at one month after treatment, using the QoL Questionnaire core 30. The scale includes five functional dimensions: body, role, emotion, cognition, and social function. A higher score suggests a better QoL.

### Statistical analysis

In the present study, the SPSS 22.0 software was used for data analysis, and GraphPad Prism 7.0 was used for image rendering and export. The significance threshold was  $P < 0.05$ . mean  $\pm$  SEM was used for statistical description of continuous variables (*e.g.*, age, tumor diameter, and CA125 expression), and the *t*-test and paired *t*-test were used for inter-group and intra-group comparisons (before and after treatment), respectively. Categorical variables (*e.g.*, sex, clinical staging, and history of alcoholism) were described by frequencies (percentages), and the comparison between groups was made using the  $\chi^2$  test.

## RESULTS

### Baseline data

As indicated by Table 1, the two patient cohorts have no evident differences in age, sex, clinical staging, tumor diameter,

**Table 1** Baseline information

Indicators	Control group (n = 30)	Research group (n = 32)	$\chi^2/t$	P value
Age (years old)	61.03 ± 6.91	61.44 ± 10.61	0.179	0.859
Gender (male/female)	17/13	19/13	0.047	0.829
Clinical staging (II/III)	18/12	16/16	0.625	0.429
Tumor diameter (cm)	5.68 ± 1.29	5.80 ± 1.50	0.337	0.738
History of alcoholism (with/without)	11/19	8/24	0.992	0.319
History of smoking (with/without)	8/22	7/25	0.194	0.660
Family medical history (yes/no)	5/25	9/23	1.163	0.281

**Table 2** Short-term efficacy of two groups of esophageal carcinoma patients, n (%)

Indicators	Control group (n = 30)	Research group (n = 32)	$\chi^2$	P value

III-IV	7 (23.33)	6 (18.75)	0.196	0.658

alcoholism history, smoking history, and family history ( $P > 0.05$ ).

### Short-term efficacy in the two patient groups

The short-term curative effects between the Res and the Con at one month after treatment were analyzed and compared (Table 2). The ORRs of the Res and the Con were determined as 62.50% and 60.00%, respectively, while the DCRs were determined as 87.50% and 83.33%, respectively, showing no significant inter-group differences in both indicators ( $P > 0.05$ ).

### Incidence of drug toxicities in the two patient groups

The main drug toxicities were MS, GI reactions, and RE, with the incidence of grade I-II MS and grade I-II GI reactions markedly lower in the Res compared with the Con ( $P < 0.05$ ; Table 3).

### Serum tumor markers in the two patient groups

Two STMSs, CA125 and MIP-3 $\alpha$ , were measured; no statistical differences were found in the corresponding pre-treatment levels between the Res and the Con ( $P > 0.05$ ); a marked reduction in both indexes was determined in the two patient cohorts, especially in the Res ( $P < 0.05$ ; Figure 1).

**Figure 1 Serum tumor markers in two groups of esophageal cancer patients.** A: The research group had markedly lower CA125 levels than the control group after treatment; B: The research group had markedly lower MIP-3α levels than the control group after treatment. <sup>a</sup>*P* < 0.05 vs control; <sup>b</sup>*P* < 0.01, vs before treatment. CA125: Carbohydrate antigen 125; MIP-3α: Macrophage inflammatory protein-3α.

**Figure 2 Angiogenesis-related indexes in two groups of esophageal cancer patients.** A: The research group had markedly lower VEGF levels than the control group after treatment; B: The research group had markedly lower VEGFR-1 Levels than the control group after treatment; C: The research group had markedly lower bFGF levels than the control group after treatment; D: The research group had markedly lower Ang-2 levels than the control group after treatment. <sup>a</sup>*P* < 0.05 vs control; <sup>b</sup>*P* < 0.01, vs before treatment. VEGF: Vascular endothelial growth factor; VEGFR-1: Vascular endothelial growth factor receptor-1; bFGF: Basic fibroblast growth factor; Ang-2: Angiogenin-2.

### Angiogenesis-related indexes in the two patient groups

The angiogenesis-related indexes VEGF, VEGFR-1, bFGF, and Ang-2, were determined in both groups for comparative analysis (Figure 2). The VEGF, VEGFR-1, bFGF, and Ang-2 Levels were similar in the two cohorts before treatment (*P* > 0.05), but their levels reduced significantly after treatment (*P* < 0.05), with even lower levels in the Res (*P* < 0.05).

### Quality of life in the two patient groups

The QoL of the two groups was compared and evaluated from five aspects: physical, role, emotional, social, and cognitive function (Figure 3). The data showed that with the exception of cognitive function, the aspect scores in the two groups increased significantly after treatment (*P* < 0.05), with more marked increases in the Res when compared with the Con (*P* < 0.05).

DOI: 10.4251/wjgo.v15.i7.1262 Copyright ©The Author(s) 2023.

**Figure 3 Quality of life of esophageal cancer patients.** A: The research group had markedly higher physical function scores than the control group after treatment; B: The research group had markedly higher role function scores than the control group after treatment; C: The research group had statistically higher emotional function scores than the control group after treatment; D: The research group had markedly higher social function scores than the control group after treatment; E: The research group had obviously higher cognitive function scores than the control group after treatment. <sup>b</sup> $P < 0.01$ , vs before treatment.

## DISCUSSION

The present study focuses on the efficacy of CCRT with THAL + S-1 for EC and its influence on patient STMs. Given the current scanty of research in this field, the present analysis is helpful in gaining a new understanding of the effectiveness of this CCRT protocol for patients with EC.

Many researchers have provided clinical references for EC treatment by analyzing relevant treatment strategies. For example, Song *et al*[15] showed that CCRT with S-1 effectively enhanced the curative effect and survival of elderly patients with non-metastatic esophageal squamous cell carcinoma compared with radiotherapy alone without increasing acute adverse reactions. As reported by McDowell *et al*[16], intensity-modulated radiotherapy combined with chemotherapy is conducive to improving the prognosis of patients with cervical EC. Ma *et al*[17] also pointed out that three-dimensional conformal radiotherapy was helpful in controlling mediastinal lymph node metastasis and recurrence after EC surgery, in addition to significantly improving the local tumor control rate and long-term survival rate. In the present study, the effectiveness of DDP + 5-FU *vs* THAL + S-1 were analyzed. The standard CCRT scheme for EC (DDP + 5-FU) still causes local failures in 46% of patients and fatal threats in 20%[18]. Hence, introducing new CCRT schemes is critical. Thalidomide can exert anti-inflammatory and immunosuppressive actions by inhibiting inflammatory factors and regulating key immunoregulatory molecules, thus exerting anti-tumor activity[19]. Among the S-1 components, tegafur is a prodrug of 5-Fu, and gimeracil can prolong the effective drug properties of 5-Fu in the blood by reducing dihydropyrimidine dehydrogenase[20].

In the present study, the Res was administered with THAL + S-1 and the Con was administered with DDP + 5-FU. The ORR and DCR of the Res were determined as 62.50% and 87.50%, respectively (slightly higher than but not significantly different from those in the Con); these results suggest equivalent curative efficacy of THAL + S-1 to that of DDP + 5-FU. Furthermore, according to the investigation of drug toxicities, the incidences of grade I-II MS and grade I-II GI reactions were identified as notably lower in the Res than in the Con, while the incidence of RE was similar, indicating the safety profile of THAL + S-1. This may be related to the inhibition of FU-related GI toxicity by oteracil potassium, one of the S-1 components[20].

Previous literature has shown a correlation of CA125 with lymph node metastasis and blood-borne metastasis of EC, as well as an association between MIP-3 $\alpha$  (also known as CCL20) and the occurrence, development, and metastasis of EC[21, 22]. While VEGF and VEGFR-1 are both significantly related to the poor prognosis of patients with EC[23], previous studies have also shown that abnormal overexpression of bFGF in advanced esophageal squamous cell carcinoma is closely associated with the development of invasive carcinoma. As a key regulator of tumor angiogenesis, Ang-2 also mediates the malignant procession of esophageal squamous cell carcinoma[24,25].

By further quantifying STMs (CA125 and MIP-3 $\alpha$ ) and angiogenesis-related indicators (VEGF, VEGFR-1, bFGF, and Ang-2) using ELISA, it was found that the post-treatment CA125, MIP-3 $\alpha$ , VEGF, VEGFR-1, bFGF, and Ang-2 Levels in the Res were evidently lower than those before treatment and the Con levels. This suggests that CCRT with THAL + S-1

has a significant inhibitory effect on STMs and angiogenesis-related indicators in patients with EC.

In the research of Wang *et al*[26], THAL validly suppressed the increase of the serum VEGF level in patients with EC during treatment; this is similar to our research results. Tsuji *et al*[27] also reported the inhibitory action of S-1 against VEGF levels in patients with metastatic breast cancer, indicating certain anti-angiogenesis activity of S-1. Finally, the QoL of the two groups after treatment was evaluated and compared regarding five aspects: physical, role, emotional, social, and cognitive function. The Res was found to have higher scores in all the other four dimensions after treatment except the cognitive function, suggesting that THAL + S-1 is more effective than DDP + 5-FU in enhancing QoL in patients with EC.

---

## CONCLUSION

Taken together, CCRT with THAL + S-1 is effective in the treatment of EC, with certain safety. This CCRT protocol has a significant inhibitory effect on STMs (CA125 and MIP-3 $\alpha$ ) and angiogenesis-related indicators (VEGF, VEGFR-1, bFGF, and Ang-2) and is conducive to improving patients' QoL, providing a new choice for clinical treatment of patients with EC. In addition, since the sample size included in the present study is limited, increasing the sample size in the future will be conducive to enhancing the credibility of the experimental results.

## ARTICLE HIGHLIGHTS

### Research background

Treatment strategies for esophageal carcinoma (EC) still need to be explored and optimized to improve patient symptoms, efficacy and prognosis.

### Research motivation

This study provided a novel and feasible scheme to improve the survival outcome of EC patients.

### Research objectives

This research intends to elucidate the clinical efficacy of concurrent chemoradiotherapy (CCRT) with thalidomide (THAL) and S-1 (tegafur, gimeracil and oteracil potassium capsules) for EC and its influence on serum tumor markers (STMs).

### Research methods

Thirty cases of EC undergoing CCRT with cis-platinum and 5-fluorouracil were assigned to the control group (Con) and 32 cases receiving CCRT with THAL and S-1 were included in the research group (Res). The efficacy, incidence of drug toxicities, STMs [carbohydrate antigen 125 (CA125), macrophage inflammatory protein-3 $\alpha$  (MIP-3 $\alpha$ )], angiogenesis-related indicators [vascular endothelial growth factor (VEGF), vascular endothelial growth factor receptor-1 (VEGFR-1), basic fibroblast growth factor, (bFGF), angiogenin-2 (Ang-2)], and quality of life [Quality of Life Questionnaire core 30, (QLQ-C30)] of the two groups were collected for comparative analysis.

### Research results

The overall response rate and disease control rate were not statistically different between the two patient cohorts, but the incidence of grade I-II myelosuppression and gastrointestinal reactions was significantly lower in the Res. In addition, the Res showed markedly reduced CA125, MIP-3 $\alpha$ , VEGF, VEGFR-1, bFGF, and Ang-2 Levels after treatment, lower than those in the Con. Moreover, a better quality of life was determined in the Res, which was supported by more significant improvements in QLQ-C30 scores from physical, role, emotional and social function dimensions.

### Research conclusions

CCRT with THAL and S-1 has a definite efficacy in the treatment of EC, which can significantly reduce CA125, MIP-3 $\alpha$ , VEGF, VEGFR-1, bFGF and Ang-2 Levels while contributing to mild toxicities, thereby inhibiting tumor malignant progression and helping to improve the quality of life of patients.

### Research perspectives

Although this study provides a new choice for the clinical treatment of EC patients by demonstrating the clinical efficacy and safety of CCRT with THAL and S-1, the credibility of our findings needs to be validated by increasing the sample size in the future due to the limited cases included in this research.
