**SPECIFIC COMMENTS TO AUTHORS**

Assessment of the risk of developing gastric cancer in patients with chronic gastritis and other underlying diseases of the stomach is important, as it makes it possible to detect this serious complication at an early stage or, in some cases, even prevent the development of gastric cancer. The authors analyzed the results of a study of 6,718 patients with gastritis and, based on the large clinical material, confirmed the possibility of stratifying patients with chronic gastritis into risk groups depending on atrophy, intestinal metaplasia, enlarged folds, nodularity, diffuse redness, and total Kyoto scores. Thus, the data obtained are of practical importance and should be taken into account when assessing the risk of developing gastric cancer in patients with chronic gastritis. A few notes to which the authors should pay attention. ABSTRACT 1. It is desirable to clarify the period during which patients were under observation RESULTS and DISCUSSION 1. (p. 9, pp. 22-23). The sentence “The annual incidence rates of GC increased with the total Kyoto score (0.05%, 0.07%, 0.47%, and 1.27% for the total Kyoto scores of 0-1, 2-3, 4, and 5-8, respectively). » Specify that we are talking about the average frequency of cases per year. This is important, because according to Figures

1-3, the highest incidence of gastric cancer is observed between 4 and 5 years for almost all studied factors. This remark also applies to other sentences where the authors talk about "annual incidence rates". 2. (p. 9, pp. 24-25). Perhaps the authors did not mean "subsequent", but "previous" studies. Table 1. 1. It is desirable to indicate the significance of differences between groups (significance level) In general, the manuscript is written in good English, well structured. Tables improve the perception of text. I believe that after minor corrections the manuscript can be published.

**SPECIFIC COMMENTS TO AUTHORS**

This is a well-conducted retrospective cohort study that investigates the incidence of gastric cancer based on the endoscopic Kyoto classification of gastritis. The study suggests that the Kyoto classification can be used to assess GC risk and that a high total Kyoto score ( $\geq 4$ ) is associated with GC incidence. The study is well designed and its findings are relevant to clinical practice. My comments are as follows: 1. Can we assume a normal distribution for the number of EGD per person and Kyoto classification score? Would it be better to use median and IQR to present this information? 2. According to your opinion, as the association between nodularity and the risk of developing GC is still debated, should nodularity be listed separately when reporting Kyoto score to emphasize its value in predicting gastric cancer? For example, should the Kyoto classification score for A1IM1H1N1DR0 be reported as 3+1 instead of 4?
