COMMENTS TO AUTHORS

Well written clinical case on the usefulness of imaging (exercise echo and CT) after a switch operation for TGA. I think that the paper would look better if the authors put the references in place, particularly references should be offered for the recommendations on angiography (introduction), AHA/ESC guidelines for adults with congenital HD (Discussion) and again in the discussion section in the next paragraph. Also it would be great to have the normal Exercise echo images (frames in systole and diastole in the 4 chamber views at rest and at exercise) with the abnormal ECG recordings on the other side. Please discuss the several coronary complications these patients may have during FU according to the literature. In the last sentence of the Discussion section, stating that half of the patients have normal stress echo and abnormal ECG findings after the switch operation, a reference is needed, or at least more information about from where this information has been taken.

COMMENTS TO AUTHORS

The authors present a case report of complete left main coronary artery occlusion after arterial switch operation in an asymptomatic 15-year-old boy. They have concluded that CCTA or CAG should be considered in patients with TGA. This manuscript is nicely structured and well written. I have no question about this manuscript.

COMMENTS TO AUTHORS

This case report presents complete coronary artery occlusion after arterial switch operation in an asymptomatic 15-year-old boy, implying that non-invasive CT angiogram to assess coronaries are preferable in pediatric patients with TGA post ASO during the follow-up of screening coronary artery occlusion, except for other methods. Two minor suggestions are as following: 1. Please add case or boy after "...15-year-old" in the title. 2. Please spell "LAD" completely in text like other acronyms.

COMMENTS TO AUTHORS

This is an interesting case that is well described and well written. While such cases are not new, with the growing population of adults with CHD, it is becoming more and more important that such cases are described as best as possible to reflect the advantages and limitations of various diagnostic tools in defining the problem

COMMENTS TO AUTHORS

Dr Saini and colleagues in their report "Complete coronary artery occlusion after arterial switch operation in an asymptomatic 15-year-old" have discussed a case of early arterial switch procedure with late diagnosis of left main occlusion. This problem had not been definitely diagnosed in isotope scanning and MRI and they've managed to evaluate it in conventional angiography and CT angiogram. I recommend this case report for its emphasis on the importance of clinical judgment and the employment of appropriate diagnostic tool when we approach to clinical and para-clinical findings. Please note to rephrase the following sentences: Abstract: "...serial screening maximal exercise stress test..." Discussion, paragraph 2: It also allows excellent assessment of the branch pulmonary arteries following the Lecompte maneuver. Discussion, paragraph 3: "...has been employed to in..." Figure legend: "CT angiographic views of from the..."
