### Abstract

Hepatitis C infection, causing cirrhosis and hepatocellular carcinoma, is an important cause of mortality and morbidity. Achieving a sustained virological response had been the major issue for decades. Interferon treatment was the primarily developed therapy against the infection. Addition of guanosine analog ribavirin in order to stop viral RNA synthesis increased the response rates as well as the adverse effects of the treatment. The increasing demands for alternative regimens lead to the development of direct-acting antivirals (DAAs). The approval of sofosbuvir and simeprevir emerged a new era of antiviral treatment in hepatitis C infection. Although majority of the studies are done
