Manuscript Type: CASE REPORT

Metallosis following a clip breakage in a total knee arthroplasty implant: A case report

Ahmed Isam Saad, Shafiq Arif Shahban, Richard Fernandes

Abstract

BACKGROUND

Metallosis describes the build-up of metal debris in the soft tissues after a period of metal on metal articulation. This debris can be asymptomatic or lead to catastrophic implant failure, which can present acutely, as in this case, or over a period of time. This report highlights how a metal clip used to hold the polyethylene liner to the tibial base plate broke 5 years after implantation, dislodged from its original position and went on to cause post-operative knee metallosis.

There are no matching sources for this report.
