COMMENTS TO AUTHORS

Despite great improvement in treatment options, the long-time survival of patients with HCC remains unsatisfactory, with a 5-year survival rate of 20 to 30% reported in the literature. The treatment of advanced and metastatic HCC presents many challenging problems. In this study, the serum from HBV infected patients was used to analyze the different disease courses of HCC. The authors investigated the correlations between miRNA and clinical pathological characterization, and our findings provide a comprehensive understanding of the molecular mechanisms of HCC and some new potential therapeutic targets. Overall, this study is well designed and the manuscript is well written. Some comments to the authors: 1 The introduction is too long. Please make a revision. Some sentences could be moved to the discussion. 2 The methods are good, and the results are interesting. But the results are not well discussed. Please discuss the results more deeply with some recent ref. 3 The manuscript needs to be proofed by a native English speaker. Some language polishing should be revised.
