SPECIFIC COMMENTS TO AUTHORS

It was observed that the type of immunosuppressive treatment did not have a significant effect on the quality of life, but it was observed that those who received tacrolimus had lower self-care and higher depression scores. Therefore, considering tacrolimus in terms of depression and self-care can be considered as an important result. It is also important to evaluate the relationship between biliary complications and quality of life. It is important that the presence of hcc before LT and the prolonging processes and procedures before finding a living donor in these patients negatively affect the quality of life. The importance of increasing the quality of life should be taken into account, since recommending such an important operation to other patients who underwent LT will significantly reduce the anxiety and depression of new patients. The situations mentioned above can be considered as the scientific contributions and new perspectives that the article offers us.

SPECIFIC COMMENTS TO AUTHORS

The article uses three evaluation scales to evaluate the mental state of patients after liver transplantation. It should be said to be objective and helpful to the clinic. If the time after transplantation is treated as a stratification, it seems more perfect.

SPECIFIC COMMENTS TO AUTHORS

Akbulut et al. present the result of a single center, retrospective, cross-sectional study evaluating quality of life parameters after liver transplantation . They found that the presence of biliary complications and hepatocellular carcinoma, low income level and monthly visits to the outpatient clinic are factors that are found to affect self-care capability, depression and anxiety. • The hypothesis of the study is not clearly explained. Overall the study is more descriptive. The authors should state the clear hypothesis and goal of their study towards the end of the introduction. • There is no clear description on the time point of analysis. It is stated that the patients that are compliant with regular out-patient follow-up were selected for evaluation however no information is given as of how long after LT did it happen. • Interquartile range (IQR) should be shown as a difference between 75th and 25th percentile. The values of both percentiles should be shown instead of a single value. • Comparison tables (4-8) should include a number of patients analyzed in both groups to improve readability. • Minor comments: the use of phrase “mental retardation” should be avoided and “intellectual disability” should be used instead. • I believe that, overall, the manuscript would benefit from minor English revisions to improve readability.
