**ABOUT COVER**

Editorial Board Member of *World Journal of Gastroenterology*, Simon Bramhall, FRCS (Gen Surg), MD, Attending Doctor, Surgeon, Consultant Upper GI/HPB Surgeon, The County Hospital, Union Walk, Hereford HR1 2ER, United Kingdom

**AIMS AND SCOPE**

The primary aim of *World Journal of Gastroenterology* (WJG, *World J Gastroenterol*) is to provide scholars and readers from various fields of gastroenterology and hepatology with a platform to publish high-quality basic and clinical research articles and communicate their research findings online.

WJG mainly publishes articles reporting research results and findings obtained in the field of gastroenterology and hepatology and covering a wide range of topics including gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, gastrointestinal oncology, and pediatric gastroenterology.

**INDEXING/ABSTRACTING**

The WJG is now indexed in Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports®, Index Medicus, MEDLINE, PubMed, PubMed Central, and Scopus. The 2019 edition of Journal Citation Report® cites the 2018 impact factor for WJG as 3.411 (5-year impact factor: 3.579), ranking WJG as 35<sup>th</sup> among 84 journals in gastroenterology and hepatology (quartile in category Q2). CiteScore (2018): 3.43.

### Abstract

Pancreatic cancer has a high mortality rate with minimal proven interventions. Intraductal Papillary Mucinous Neoplasms (IPMNs) are known precursor lesions for pancreatic cancer. Identification of pancreatic cysts has improved from advances in abdominal imaging. Despite multiple revisions of the international consensus recommendations and various guidelines by other major societies, successful risk stratification of the malignant potential of mucinous pancreatic cysts remains challenging. Specifically, detection and accurate classification of advanced neoplasia (high-grade dysplasia and/or adenocarcinoma) in IPMNs is suboptimal with current diagnostic strategies. Development of interventional techniques utilizing endoscopic ultrasound include - through-the-needle microforceps biopsy, next-generation or whole genome molecular analysis of cyst fluid, and needle-based confocal laser endomicroscopy. These techniques suffer from a series of limitations in technical success, diagnostic yield, and clinical feasibility, but a combination approach may offer a solution that optimizes their cyst evaluation and risk stratification. Assessment and comparison of these techniques is restricted by lack of adequate surgical specimens for testing of diagnostic accuracy, resulting in a possible sample bias. Additional large-scale multicenter studies are needed to accumulate evidence for the utility and feasibility of their translation into clinical practice. Great strides have been made in pancreatic cyst evaluation, but further research is required to improve diagnostic accuracy and clinical management of IPMNs.

**Key words:** Pancreatic cyst; Confocal endomicroscopy; Microforceps biopsy; Cyst fluid molecular analysis; Endoscopic ultrasound; Intraductal papillary mucinous neoplasms

**Core tip:** Current International Consensus Guidelines for the assessment of pancreatic cysts are insufficient in the detection of advanced neoplasia in intraductal papillary mucinous neoplasms. This manuscript summarizes the advances in endosonographic methods aiming to address this critical need and suggests additional research is necessary for more conclusive clinical management recommendations.

## INTRODUCTION

Advances in abdominal imaging techniques have led to an increase in detection and diagnosis of pancreatic cystic lesions (PCLs)<sup>[1,2]</sup>. Although the majority of pancreatic cysts are asymptomatic and do not progress to adenocarcinoma, the ability to differentiate precancerous versus benign lesions and further estimate the risk for malignant transformation of precancerous lesions remains a challenge in the field<sup>[1,3]</sup>. Among all solitary PCLs, branch duct (BD) intraductal papillary mucinous neoplasms (IPMN) are the most common type of precancerous lesions, and are often referred for surveillance due to their low chance of progressing to cancer<sup>[1,4]</sup>. However, even with the use of international consensus guidelines (ICG) for the evaluation of mucinous PCLs, advanced neoplasia (high grade dysplasia or adenocarcinoma) is frequently missed<sup>[5]</sup>. Moreover, surgery for PCLs must be highly selective since the risk of long-term significant morbidity is 30% with a 2.1% mortality rate<sup>[1,6]</sup>. Thus, a sensitive and accurate method measuring risk for advanced neoplasia in BD-IPMNs is critical to determine an optimal timeline for intervention for lesions that can potentially progress to adenocarcinoma.

Reflecting on morbidity rates for cyst resection, the recommendation of resection is becoming more heavily scrutinized. Determining the presence of low-grade or high-grade dysplasia informs the need and urgency for intervention, but evaluating dysplasia with current assessment methods remains a challenge<sup>[1]</sup>. A study by Sahara *et al*<sup>[7]</sup> found that an estimated 75% of resected IPMNs were evaluated as low grade dysplasia that could have instead been monitored<sup>[7]</sup>. Additional studies have reported that for patients identified as having high-grade dysplasia, early identification significantly improved survival rates and eliminated or reduced risk for recurrence<sup>[1,8,9]</sup>. Thus, advances in identifying the risk and rate of transformation to advanced neoplasia could inform the ideal point for surgical intervention<sup>[10]</sup>.

Risk assessment techniques in the field are lacking methods that can be used with frequency, possess excellent sensitivity and specificity, and are minimally invasive. First line assessment includes imaging techniques, followed by more invasive imaging or biopsy methods *via* endoscopic ultrasound (EUS)<sup>[1]</sup>. Computed tomography and magnetic resonance imaging technology provide abdominal imaging to characterize the cyst type and preemptively assess for the presence of high-risk or concerning features<sup>[1,11]</sup>. Cyst morphology on EUS imaging has similar accuracy in diagnosing a benign from malignant cyst to that of magnetic resonance imaging but is more invasive<sup>[1]</sup>. Additional methods that use EUS-guided technology can include fine needle aspiration (FNA), through-the-needle microforceps biopsy (EUS-MFB), and needle-based confocal laser endomicroscopy (EUS-nCLE). Advances in these techniques aim to address the critical need to assess risk for malignant transformation in IPMNs. These techniques and their feasibility for clinical adaptation will be summarized in this review.

## HOW DO THE GUIDELINES PERFORM?

Clinical guidelines assist in the identification of advanced neoplasia in PCLs. The major society guidelines include 2012 and 2017 revised ICG, 2015 American Gastroenterological Association (AGA) guidelines, and the 2018 American College of Gastroenterology guidelines<sup>[11,12]</sup>. Changes in guidelines have improved identification of advanced neoplasia in IPMNs. Sighinolfi *et al*<sup>[13]</sup> retrospectively validated the 2006

ICG, 2012 ICG, and AGA criteria, where the 2012 ICG and AGA showed significantly improved specificity (58.2% and 62.4%, respectively) and diagnostic accuracy (67% and 68%, respectively) for advanced neoplasia compared to the 2006 ICG (specificity 32.7%, diagnostic accuracy 46%)<sup>[13]</sup>. Additionally, Kang *et al*<sup>[14]</sup> have demonstrated superior diagnostic performance of the 2017 ICG [area under the curve (AUC) 0.78] compared to 2012 ICG criteria (AUC 0.74) for the detection of malignancy in BD-or mixed-type IPMNs<sup>[14]</sup>. Yet, these consensus opinions remain suboptimal, and there is need for improved cyst surveillance methods and timing of surgical intervention.

## ENDOSCOPIC ULTRASOUND-GUIDED METHODOLOGY FOR RISK STRATIFICATION OF INTRADUCTAL PAPILLARY MUCINOUS NEOPLASMS

### *Molecular analyses of cyst fluid*

Cystic fluid carcinoembryonic antigen (CEA) acquired from EUS-FNA reflects a pooled 66% specificity and 65% sensitivity in identifying mucinous PCLs, yet it is not helpful in differentiating low-*vs* high-grade dysplasia<sup>[1,15,16]</sup>. Overall, EUS-FNA has moderate diagnostic strength in identifying benign and malignant lesions, but lacks ability to monitor risk and progression of advanced neoplasia in the absence of obvious EUS-imaging morphological features of malignancy<sup>[17]</sup>. However, building on the use of this technique, as well as addressing its limitations, recent research has advanced to integrate the use of molecular and genetic testing from acquired cyst fluid as a potential solution for risk assessment<sup>[18]</sup>.

Using analysis of DNA or miRNA mutations *via* algorithms developed with whole-genome sequencing techniques, distinct genetic profiles have been developed to identify risk for malignant transformation from cystic fluid (Table 1)<sup>[1,19,20]</sup>. Mutations in *KRAS* and *GNAS* have been specifically targeted, with 100% sensitivity and 96% specificity for the detection of IPMN. In addition, these mutations resulted in an 89% sensitivity and 100% specificity for IPMN and mucinous cystic neoplasms combined<sup>[1,18]</sup>.

Combination *KRAS*/*GNAS* with additional mutations in *TP53*, *PIK3CA*, and *PTEN* showed 88% sensitivity, 97% specificity for IPMN with advanced neoplasia<sup>[18]</sup>. Additional mutations in *TP53*, *PIK3CA*, and *PTEN* testing showed 79% sensitivity, 96% specificity for all mucinous pancreatic cysts with advanced neoplasia, showing potential for the role of molecular analyses in risk stratification of cysts. Other genes that have proven useful in risk stratification of IPMNs include *SMAD4*, *RNF43*, and *CDKN2A*<sup>[18,21]</sup>.

The benefits of such a technique address some of the previous sampling limitations of EUS-FNA CEA analysis, as molecular analysis uses a very small amount of cyst fluid (0.25 mL fluid) and can be helpful when aspirated volume is an issue<sup>[22]</sup>. However, challenges with this technique include – reproducibility (replicating single center results in multicenter prospective studies), and feasibility for general hospitals<sup>[23]</sup>. Further, studies to date exploring the molecular markers have often used post-resected biologic specimens, thus creating the possibility for bias in the pathology of samples. Additional studies are needed to identify an adequate panel of genes for assessment of pancreatic cysts<sup>[18]</sup>. Results were also cross-validated using standard techniques such as cytology/CEA, whose sampling errors often results in discordant pairs of specimens for correlation, given challenges in diagnostic yield<sup>[17]</sup>. Major advancements in this method have yet to solve the problem of monitoring risk for progression to advanced neoplasia, but its feasibility for repeated usage in clinical surveillance is optimistic<sup>[17]</sup>.

### *EUS-guided microforceps biopsy*

A relatively novel procedure, EUS-MFB utilizes through-the needle microforceps to acquire a tissue biopsy from PCLs for histologic analysis (Table 2)<sup>[24]</sup>. There is paucity of large, randomized trials evaluating EUS-MFB in PCLs; however, multiple systematic reviews and meta-analyses have sought to further evaluate the utility of this device. Most of these studies (Table 2) address only diagnostic yield without the estimation of diagnostic accuracy. Tacelli *et al*<sup>[25]</sup> reviewed 9 studies evaluating EUS-MFB; technical success was achieved in 98.5% [95% confidence interval (CI): 97.3%-99.6%,  $I^2$  (measure of heterogeneity) = 88.6%], specimen adequacy was achieved in 86.7% (95%CI: 80.1%-93.4%,  $I^2$  = 84.3%), the pooled diagnostic yield was 69.5% (95%CI: 59.2%-79.7%,  $I^2$  = 84.7%;  $P$  < 0.001), and pooled rate of adverse events was 8.6%<sup>[25]</sup>. Another recent meta-analyses by Facciorusso *et al*<sup>[26]</sup>, involving 11 studies, revealed that specimen adequacy was 85.3% (95%CI: 78.2%-92.5%,  $I^2$  = 41.5%), pooled diagnostic accuracy (8 of 11 studies) was 78.8% (95%CI: 73.4%-84.2%,  $I^2$  = 28.4%), and

Table 1 Comparison of molecular analyses to resected specimen<sup>[23]</sup>

Ref.	Design	Sample	Specific cyst type (NGS/surgery)					Sensitivity/ specificity	Key findings
			IPMN-Ca	IPMN-HGD	IPMN-LGD	MCN-HGD	MCN-LGD		
Springer <i>et al</i> <sup>[22]</sup> , 2015	Retrospective, multi-center, whole genome sequencing algorithm	<i>n</i> = 130 patients with surgical pathology	NA/12	NA/22	NA/62	-	NA/12	NGS identified IPMNs with 76% sensitivity and 97% specificity from presence of mutation in <i>GNAS</i> , <i>RNF43</i> , <i>LOH</i> in chromosome 9, or aneuploidy in chromosome 1q or 8p	Use of this molecular algorithm can avoid unnecessary surgery and is relatively sensitive for high risk cysts. Adding clinical markers and radiologic features improved sensitivity to 94% but decreased specificity to 84%
Singhi <i>et al</i> <sup>[16]</sup> , 2016	Retrospective, molecular testing of cyst fluid with novel algorithmic pathway	<i>n</i> = 225 patients; <i>n</i> = 41 patients with surgical pathology	9/9	1/2	12/12	-	1 <sup>2</sup> /1	Six cancer genes targeted <i>KRAS</i> / <i>GNAS</i> sensitivity 100%, specificity 100% for IPMN, <i>TP53</i> , <i>PIK3CA</i> , and/or <i>PTEN</i> sensitivity 91%, specificity 97% for IPMN with advanced neoplasia	Integrating molecular testing with clinical features and cytopathology into algorithm resulted in sensitivity and specificity for advanced neoplasm of 100% and 90%, respectively
Jones <i>et al</i> <sup>[49]</sup> , 2016 <sup>1</sup>	Prospective, NGS	<i>n</i> = 79 patients (92 PCL samples), <i>n</i> = 14 with surgical pathology	1/4	0/2	4/4	-	-	Thirty-nine cancer genes targeted, specificity and sensitivity for NGS was 75% and 86%, specificity and sensitivity for CEA was 100% and 57%, NGS was more sensitive but CEA was more specific for identifying mucinous etiology	A <i>KRAS</i> mutation reclassified 19% of cysts as mucinous that were originally identified as nonneoplastic and nonmucinous from CEA, 20% of cysts identified as nonmucinous by imaging were identified as mucinous by NGS. A <i>KRAS</i> / <i>GNAS</i> mutation correlated with nonmucinous CEA in 71% of IPMNs

Rosenbaum <i>et al</i> <sup>[50]</sup> , 2016	Retrospective, NGS	<i>n</i> = 113 PCL samples (105 patients); <i>n</i> = 25 patients with surgical pathology	NA	NA	NA	NA	NA	NA	Nine cancer genes targeted, Detection of a <i>KRAS</i> variant yielded 80% sensitivity and 88% specificity for IPMN or carcinoma. <i>GNAS</i> variant yielded 27% sensitivity and 100% specificity for IPMN or carcinoma.	Combining cytology, CEA, and NGS yielded a 90% sensitivity and 88% specificity for IPMN or carcinoma.
Singhi <i>et al</i> <sup>[18]</sup> , 2018	Prospective, FNA of cyst fluid with NGS	<i>n</i> = 626 PCL samples from 595 patients; <i>n</i> = 102 patients with surgical pathology	13/13	4/4	39/39	0/2	2/8		Eleven cancer genes targeted, <i>KRAS</i> / <i>GNAS</i> sensitivity 100%, specificity 96% for detection of IPMN; and 89% sensitive and 100% specific for IPMN and MCNs combined, Combination <i>KRAS</i> / <i>GNAS</i> with <i>TP53</i> , <i>PIK3CA</i> , and <i>PTEN</i> testing showed 88% sensitivity, 97% specificity for IPMN with advanced neoplasia, Combination <i>KRAS</i> / <i>GNAS</i> with <i>TP53</i> , <i>PIK3CA</i> , and <i>PTEN</i> testing showed 79% sensitive, 96% specific for all mucinous pancreatic cysts with advanced neoplasia	Mutant allele frequencies over 55% for <i>GNAS</i> correlated with IPMNs with <i>HGD</i> , even if no <i>TP53</i> / <i>PIK3CA</i> / <i>PTEN</i> mutations were detected, Preoperative NGS could be used to classify PCs and detect IPMNs with advanced neoplasia

<sup>1</sup>No reported mutant allele frequencies which may impact risk stratification for 2 high-grade dysplasia intraductal papillary mucinous neoplasm.

<sup>2</sup>Identified by alterations in *TP53*, *PIK3CA* and/or *PTEN*; not *KRAS* or *GNAS*. IPMN: Intraductal papillary mucinous neoplasm; IPMN-Ca: IPMN with adenocarcinoma; HGD: High-grade dysplasia; LGD: Low-grade dysplasia; NGS: Next-generation sequencing; CEA: Carcinoembryonic antigen; NA: Not available.

risk of adverse events was 8.98%<sup>[26]</sup>. In a study by Larghi *et al*<sup>[27]</sup>, where EUS-MFB specimens (*n* = 40) were retrieved and evaluated by pathologists (*n* = 6), the interobserver agreement among pathologists was almost perfect for specimen adequacy (Gwet's AC1 0.82, 95%CI: 0.79-0.98), and substantial for the diagnosis of PCL (AC1 0.62, 95%CI: 0.57-0.67)<sup>[27]</sup>.

EUS-MFB likely solves the problems of low cellular cystic fluid acquisition by instead sampling tissue from the epithelium lining the cyst wall, as well as tissue beyond the epithelium<sup>[25,28]</sup>. It has been demonstrated that obtaining two macroscopically visible tissue samples reached optimal histologic adequacy and specifically, identification of stroma beyond the epithelium greatly assists in diagnosis

Table 2 Comparison of endoscopic ultrasound-guided microforceps biopsy to resected specimen<sup>[23]</sup>

Ref.	Design	Sample	Specific cyst type (MFB/surgery)					Results	Additional key findings
			IPMN-Ca	IPMN-HGD	IPMN-LGD	MCN-HG	MCN-LG		
Basar <i>et al</i> <sup>[51]</sup> , 2018	Retrospective, open label, multicenter; MFB	<i>n</i> = 42 patients; <i>n</i> = 7 surgical pathology	2/2	0/0	1/1	-	0/1	Cystic tissue acquisition yield 90% MFB <i>vs</i> 88.1% FNA. Diagnostic yield was 61.9% MFB <i>vs</i> 47.6% CFC	Specific cyst type diagnosis provided by MFB 35.7% <i>vs</i> CFC 4.8%
Kovacevic <i>et al</i> <sup>[31]</sup> , 2018	Retrospective, MFB	<i>n</i> = 31 patients; <i>n</i> = 18 FNA cytology; <i>n</i> = 4 surgical pathology	0/1	0/0	3 <sup>1</sup> /2	-	-	Technical success for MFB 87.1% <i>vs</i> 58.1% FNA. Diagnostic yield 71% MFB <i>vs</i> 35.5% CFC	MFB yielded change in clinical management in 19.4% of cases
Mittal <i>et al</i> <sup>[52]</sup> , 2018	Retrospective, EUS-MFB	<i>n</i> = 27 patients	0/0	0/0	1 <sup>2</sup> /3	NA	NA	Technical success 100% EUS-MFB; Diagnostic yield 88.9% EUS-MFB	MFB altered diagnosis in 26% of cases. However, cytology diagnosed 4 mucinous cysts (14.8%) that MFB missed
Yang <i>et al</i> <sup>[53]</sup> , 2018	Retrospective, EUS-MFB	<i>n</i> = 47 patients; <i>n</i> = 8 surgical pathology	0/0	2/2	4 <sup>3</sup> /5	-	-	Technical success EUS-MFB 85.1% <i>vs</i> 48.9% FNA	Mucinous cysts were diagnosed more often by EUS-MFB (34.3%) compared to FNA + CEA analysis combined (9.4%); FNA diagnosed adenocarcinoma for 1 patient, but was benign <i>via</i> EUS-MFB and surgical resection
Zhang <i>et al</i> <sup>[54]</sup> , 2018	Retrospective, MFB	<i>n</i> = 48 patients	1 <sup>4</sup> /3	1 <sup>1</sup> /0	4/4	-	0/1	Diagnostic yield MFB 75.0% <i>vs</i> 72.9% CFC	Specific cyst type diagnosis was successful 50.0% MFB <i>vs</i> 18.8% for FNA cytology; Three times as many IPMNs were diagnosed by MFB alone compared to CFC

Crinò <i>et al</i> <sup>[55]</sup> , 2019	Retrospective, EUS-MFB	<i>n</i> = 61 patients	-	-	-	0/1	11/12	Diagnostic reliability of EUS-MFB compared to surgery was 90% <i>vs</i> 20% CFC	Two EUS-MFB histologic samples resulted in a specific cyst diagnosis in 74% of cases; 100% histological adequacy reached with two EUS-MFB samples
Yang <i>et al</i> <sup>[24]</sup> , 2019	Prospective, Open Label, EUS-MFB	<i>n</i> = 114 patients; <i>n</i> = 23 surgical pathology	2/2	2/2	5/5	3/3	1/1	Specificity for EUS-MFB was 100% <i>vs</i> 21.4% CFC; EUS-MFB was diagnostic to the degree of dysplasia by 80% <i>vs</i> 0% CFC	Tissue acquisition reached 83.3% with EUS-MFB <i>vs</i> 37.7% with FNA; Findings from EUS-MFB were 100% concordant with analysis from resection <i>vs</i> 21.4% with CFC alone

<sup>1</sup>False negative by micro-forceps biopsy, surgery identified as adenocarcinoma.

<sup>2</sup>Cysts classified as mucinous, but not differentiated into intraductal papillary mucinous neoplasm or mucinous neoplasm.

<sup>3</sup>Intraductal papillary mucinous neoplasms with no dysplasia subtype were grouped as intraductal papillary mucinous neoplasm low-grade dysplasia.

<sup>4</sup>Undiagnostic on micro-forceps biopsy. IPMNs: Intraductal papillary mucinous neoplasms; IPMN-Ca: IPMN with adenocarcinoma; HGD: High-grade dysplasia; LGD: Low-grade dysplasia; MFB: Micro-forceps biopsy; CFC: Cystic fluid cytology; FNA: Fine needle aspiration; MCN: Mucinous neoplasm; NA: Not available.

of mucinous cystic neoplasms<sup>[29,30]</sup>. Additionally, a study by Kovacevic *et al*<sup>[31]</sup> posited EUS-MFB may be used to subtype IPMNs according to mucin expression, leading to more accurate risk stratification, but the scope of the study was limited and additional research and follow up is needed<sup>[31]</sup>.

Although EUS-MFB carries improvements in tissue acquisition and thus advances in diagnostic yield from samples, there are increased reports of adverse events (pooled estimate of 8.6%, with limited serious adverse events), but this might be related to operator skill<sup>[25]</sup>. The benefit for obtaining tissue for histology may lead to further advantages for this technique, however it is important to note that the biopsies are obtained from focal areas in the cyst, due in part to the stiffness of the 19-g needle with the forceps<sup>[25]</sup>. It is also noted that there are concerns for gastric seeding using this technique, and thus its clinical safety and feasibility imply the need for additional testing<sup>[11]</sup>.

Studies utilizing EUS-MFB have addressed the diagnostic yield, feasibility, technical success, and associated adverse events. However, there are no comparative large prospective studies with assessment of diagnostic accuracies where the reference standard is surgical histopathology and the lack of this diminishes the full impact of this novel diagnostic modality in the management of PCLs.

### **EUS guided needle confocal laser endomicroscopy**

EUS guided needle confocal laser endomicroscopy is a novel *in vivo* imaging technique that grants real-time, high-resolution microscopic imaging of the pancreatic cyst epithelium. Major trials (INSPECT, DETECT, CONTACT, and INDEX) have established feasibility, diagnostic image standard, and characteristic CLE patterns of pancreatic cysts routinely evaluated in clinical practice<sup>[32-37]</sup>. In the INDEX study, investigators confirmed the *in vivo* nCLE features on *ex vivo* post-resection specimens of IPMNs<sup>[38,39]</sup>, and also validated EUS-nCLE image patterns of mucinous PCLs including IPMNs among blinded external CLE-expert observers<sup>[40]</sup>. In a post-hoc analysis of the INDEX study, quantification of the papillary epithelial width and darkness (pixel intensity) was able to predict advanced neoplasia in IPMNs (Figure 1). The study included 26 IPMNs (high-grade dysplasia-Ca in 16) with histopathological (*n* = 24) or cytological (*n* = 2) reference standard. For diagnosing advanced neoplasia, CLE features of increased papillary epithelial “width” with cut-off value of  $\geq 50 \mu\text{m}$  revealed a sensitivity, specificity, and AUC of 87.5%, 100%, and 0.95, respectively.

Similar diagnostic values of sensitivity, specificity, and AUC of 87.5%, 100%, and 0.95, respectively, were observed for papillary darkness (pixel-intensity) cut-off value  $\leq 90$  pixels (lower values being darker). The pathology of IPMNs presents a papillary configuration that includes a spectrum of dysplastic mucinous epithelium ranging from low-to-high grade dysplasia<sup>[41,42]</sup>. While low-grade dysplasia demonstrates a single flat layer of columnar cells with retained polarity, high-grade dysplasia demonstrates loss of nuclear polarity, increased nuclear-cytoplasmic ratio, stratification of both the columnar cells and their nuclei, and complex architecture<sup>[41]</sup>. In parallel to these pathological changes, IPMNs with low-grade dysplasia reveal a thin layer of epithelium (Figure 1), whereas advanced neoplasia reveals thicker and darker epithelium since CLE imaging of the nuclei reveals dark spots, which when stratified imparts a darker hue to the epithelium. Thus, the consequence of a combination of cellular and nuclear stratification is thicker and darker epithelium of the papillae (Figure 1). Qualitative image interpretation by an endoscopist is susceptible to interobserver disagreement and quantitative estimation of papillary thickness and darkness can be laborious. Hence, computer-aided quantification utilizing machine learning and artificial intelligence would need to be adapted to reduce interobserver disagreement and endoscopist work load.

Similar to other EUS-guided evaluations, nCLE differentiation of dysplasia in IPMN needs to be reproducible and validated in prospective multi-center studies. If endomicroscopy assisted machine learning and artificial algorithms are generated, these would need to be validated in multicenter studies across multiple centers and endoscopists. Since the entire cyst is not imaged during CLE, theoretically the modality cannot be utilized to rule-out advanced neoplasia in IPMNs. Despite the limitations in the maneuverability of the EUS-FNA needle (19-g), approximately 30%-50% of the PCLs can be observed depending on the location of the neoplasm in the pancreas.

## CONCLUSION

Pancreatic adenocarcinoma is a near fatal diagnosis with a  $< 10\%$  5-year overall survival rate, and there are no pragmatic investigations for screening with proven efficacy<sup>[43]</sup>. Analogous to other adenocarcinomas such as esophageal and colorectal cancer, the resection of a premalignant lesion such as IPMN should prevent development of pancreatic adenocarcinoma; however, the operative morbidity of pancreatic surgery is high, the natural history of BD-IPMNs ( $< 3$  cm) has not been delineated, and it is challenging to diagnose BD-IPMNs with advanced neoplasia<sup>[11]</sup>. Despite multiple revisions of the international consensus guidelines and various guidelines by other major societies<sup>[11,12,44,45]</sup>, there continues to be range of percentage of patients (up to 2/3<sup>rd</sup> of resections at tertiary care centers) who have low-grade dysplasia on postoperative pathology<sup>[46-48]</sup>.

Improved diagnostics are needed that are sensitive and accurate in identifying dysplasia, as well as informing an appropriate timeline for intervention when considering risk of malignant transformation. Each of the methods explored in this manuscript, through-the-needle tissue biopsy/MFB, molecular analysis, and nCLE, have attempted to address this need. Collectively these methods suffer from potential sample bias given the limited amount of surgical specimen pathology available to confirm diagnostic accuracy. There is inherent need for improved sample size to refine these methods, which will likely only be attained from large-scale multisite studies. These methods each have individual limitations, and it may be prudent to evaluate a combination of techniques to optimize clinical feasibility and diagnostic accuracy. In summary, great strides have been made in the evaluation of pancreatic cysts, but there is still a critical need for further research to classify the risk for malignant potential.

**Figure 1** Endoscopic ultrasound-guided confocal endomicroscopy characteristics of intraductal papillary mucinous neoplasm. A-C: Intraductal papillary mucinous neoplasm with low-grade dysplasia. Papillae (blue arrows) reveal thin and translucent epithelium. The papillae are small with thin epithelium in panel A. The epithelium is flat in panels B and C; D-H: Intraductal papillary mucinous neoplasm with high-grade dysplasia. Papillae (orange arrows) show thicker and darker epithelium. In panel D, there is higher density of papillae.

Trends in management and outcome of cystic pancreatic lesions - analysis of 322 cases undergoing surgical resection. *Scand J Gastroenterol* 2019; **54**: 1051-1057 [PMID: [31322457](#) DOI: [10.1080/00365521.2019.1642379](#)]
- 48 **Vaalavuo Y**, Anttila A, Ahola R, Siiki A, Vornanen M, Ukkonen M, Sand J, Laukkanen J. Characteristics and long-term survival of resected pancreatic cystic neoplasms in Finland. The first nationwide retrospective cohort analysis. *Pancreatolgy* 2019; **19**: 456-461 [PMID: [30808537](#) DOI: [10.1016/j.pan.2019.02.007](#)]
- 49 **Jones M**, Zheng Z, Wang J, Dudley J, Albanese E, Kadayifci A, Dias-Santagata D, Le L, Brugge WR, Fernandez-del Castillo C, Mino-Kenudson M, Iafrate AJ, Pitman MB. Impact of next-generation sequencing on the clinical diagnosis of pancreatic cysts. *Gastrointest Endosc* 2016; **83**: 140-148 [PMID: [26253016](#) DOI: [10.1016/j.gie.2015.06.047](#)]
- 50 **Rosenbaum MW**, Jones M, Dudley JC, Le LP, Iafrate AJ, Pitman MB. Next-generation sequencing adds value to the preoperative diagnosis of pancreatic cysts. *Cancer Cytopathol* 2017; **125**: 41-47 [PMID: [27647802](#) DOI: [10.1002/cncy.21775](#)]
- 51 **Basar O**, Yuksel O, Yang DJ, Samarasena J, Forcione D, DiMaio CJ, Wagh MS, Chang K, Casey B, Fernandez-Del Castillo C, Pitman MB, Brugge WR. Feasibility and safety of microforceps biopsy in the diagnosis of pancreatic cysts. *Gastrointest Endosc* 2018; **88**: 79-86 [PMID: [29510146](#) DOI: [10.1016/j.gie.2018.02.039](#)]
- 52 **Mittal C**, Obuch JC, Hammad H, Edmundowicz SA, Wani S, Shah RJ, Brauer BC, Attwell AR, Kaplan JB, Wagh MS. Technical feasibility, diagnostic yield, and safety of microforceps biopsies during EUS evaluation of pancreatic cystic lesions (with video). *Gastrointest Endosc* 2018; **87**: 1263-1269 [PMID: [30347425](#) DOI: [10.1055/a-0732-5356](#)]

- 29309781 DOI: [10.1016/j.gie.2017.12.025](https://doi.org/10.1016/j.gie.2017.12.025)]
- 53 **Yang D**, Samarasena JB, Jamil LH, Chang KJ, Lee D, Ona MA, Lo SK, Gaddam S, Liu Q, Draganov PV. Endoscopic ultrasound-guided through-the-needle microforceps biopsy in the evaluation of pancreatic cystic lesions: a multicenter study. *Endosc Int Open* 2018; **6**: E1423-E1430 [PMID: [30574535](https://pubmed.ncbi.nlm.nih.gov/30574535/) DOI: [10.1055/a-0770-2700](https://doi.org/10.1055/a-0770-2700)]
- 54 **Zhang ML**, Arpin RN, Brugge WR, Forcione DG, Basar O, Pitman MB. Moray micro forceps biopsy improves the diagnosis of specific pancreatic cysts. *Cancer Cytopathol* 2018; **126**: 414-420 [PMID: [29660844](https://pubmed.ncbi.nlm.nih.gov/29660844/) DOI: [10.1002/cncy.21988](https://doi.org/10.1002/cncy.21988)]
- 55 **Crinò SF**, Bernardoni L, Brozzi L, Barresi L, Malleo G, Salvia R, Frulloni L, Sina S, Parisi A, Remo A, Larghi A, Gabbrielli A, Manfrin E. Association between macroscopically visible tissue samples and diagnostic accuracy of EUS-guided through-the-needle microforceps biopsy sampling of pancreatic cystic lesions. *Gastrointest Endosc* 2019; **90**: 933-943 [PMID: [31100310](https://pubmed.ncbi.nlm.nih.gov/31100310/) DOI: [10.1016/j.gie.2019.05.009](https://doi.org/10.1016/j.gie.2019.05.009)]
