Abstract

AIM: To compare defecographic abnormalities in symptomatic men and women and to analyze differences between men and age- and symptom-matched women.

METHODS: Sixty-six men (mean age: 55.4 years, range: 20-81 years) who complained of constipation and/or fecal incontinence and/or pelvic pain underwent defecography after intake of a barium meal. Radiographs were analyzed for the diagnosis of rectocele, enterocele, intussusception and perineal descent. They were compared with age- and symptom-matched women ($n = 198$) who underwent defecography during the same period.

RESULTS: Normal defecography was observed in 22.7% of men vs 5.5% of women ($P < 0.001$). Defecography in men compared with women showed 4.5%

vs 44.4% ($P < 0.001$) rectocele, and 10.6% vs 29.8% ($P < 0.001$) enterocele, respectively. No difference was observed for the diagnosis of intussusception (57.6% vs 44.9%). Perineal descent at rest was more frequent in women ($P < 0.005$).

CONCLUSION: For the same complaint, diagnosis of defecographic abnormalities was different in men than in women: rectocele, enterocele and perineal descent at rest were observed less frequently in men than in women.

INTRODUCTION

Constipation, fecal incontinence and pelvic pain require meticulous evaluation because therapy can be effective and help patients to lead a fuller life. Radiographic dynamic rectal examination (defecography) is a valuable method to assess evacuation disorders^[1-5]. This method provides precise information on anorectal and pelvic floor functions^[6-8]. It can be used to evaluate efficiently defecation disorders after clinical examination for the exploration of constipation, pelvic pain and anal incontinence^[9-13].

Posterior pelvic floor disorders are common and well known in women, and some are related to obstetrical consequences. Little is known about gender influence in symptomatic patients investigated by defecography^[14,15]. Men can also complain of constipation, fecal incontinence and pelvic pain, and these symptoms need the same careful evaluation because they may need specific therapy^[16].

The purpose of our study was to compare prevalence of defecographic abnormalities in men and age- and symptom-matched women.

MATERIALS AND METHODS

Patients

Over a 6-year period, 66 symptomatic aged 20-81 years (mean \pm SD: 55.4 \pm 14.9 years) addressed for defecography were evaluated consecutively in our institution. All patients were referred by a gastroenterologist or a digestive tract surgeon for the exploration of constipation, pelvic pain or fecal incontinence. Constipation was defined as less than two bowel movements per week. Fecal incontinence was defined by an uncontrolled loss of liquid or solid stools that corresponded to grade C and D of Park's classification^[17].

To compare defecographic abnormalities in men with women, a case-matched series was isolated from a prospective database of women ($n = 700$) investigated by defecography in the same period with the same techniques. Three women for one man were isolated. A series of 198 age- and symptom-matched women was studied. A value of 0 (absence) or 1 (presence) was attributed to each of the three types of symptoms (constipation, anal incontinence or pelvic pain) for all the patients in the database. Several age groups (5-years periods) were isolated for both genders. In these groups of similar age, three women with the same combination of symptoms were associated with one man. The choice of the symptom-matched women was done blindly of the results of the defecography from a global database that contained all the symptomatic patients who underwent defecography during this period in our unit. For example, for a 63-year-old man with constipation and pelvic pain (values = 1/0/1), three women (aged 60-65 years) with the same combination (1/0/1) were isolated. The women were aged 20-81 years (mean: 55.1 \pm 14 years).

Defecography

We applied a standardized protocol to perform and evaluate all defecography examinations. All patients received a barium meal 1.5 h before the examination to opacify the pelvic small bowel for the detection of enterocele. A lateral X-ray was first performed for bone and pelvic loop visualization. In women, a thick barium paste was injected into the vagina, to mark out the posterior vaginal wall. Then, 150 mL of thickened and viscous high-density barium contrast medium was injected in the rectum with the patient in the left lateral position.

Films were taken in a standing lateral position during the following maneuvers: at rest, at voluntary and maximal contraction of the sphincter and pelvic floor ("squeeze"), and at straining without defecation ("strain"). The pubococcygeal line was defined and the distance between this line and the anorectal junction was determined for the three positions. Finally, patients sat on an upright commode attached to the footboard of the fluoroscopy table (a modified toilet), and one frame per second films were taken during expulsion and after completion of defecation at maximum straining.

Precise explanations of the entire procedure were given by the radiologist prior to defecography. In young women, defecography was always performed during the first part of the cycle. Image analysis was done by one of the senior radiologists involved in this study (CSC or EK).

Pathological patterns were defined as follows. Pelvic floor descent was assessed from standing lateral views during maneuvers. For the diagnosis of perineal descent at rest, the distance in millimeters between the anorectal junction and the pubococcygeal line was noted. Perineal descent at rest was defined as a distance of > 30 mm. For perineal descent at straining, the difference in millimeters between the anorectal junction position at straining and at rest was noted. Perineal decent at straining was defined as a difference of > 20 mm between the two positions. The number of male and female patients with perineal descent at rest was compared. Anterior rectocele was defined as > 30 mm outpouching of the anterior rectal wall. This outpouching should persist on incomplete evacuation. Intussusception was defined as an invagination of the rectal wall, either intrarectal, intra-anal, or an external prolapse of the whole circumference. Enterocele was defined as herniation of the small bowel between the vaginal posterior wall and the anterior rectal wall.

Statistical analysis

χ^2 tests were used for the comparison of rectocele, enterocele, perineal descent and intussusception. $P < 0.05$ was regarded as significant.

RESULTS

Constipation, fecal incontinence and pelvic pain were present in 69%, 27% and 56% of our male patients, respectively. These symptoms could be isolated (53%) or associated (Figure 1). The more frequent association was constipation and pelvic pain (33%).

Defecography could be satisfactorily performed in all patients and all examinations could be analyzed fully with the above-described criteria. In men, 22.7% of the defecography procedures were normal versus 5.5% in women ($P < 0.001$).

Defecography in men showed intussusception in 38 patients (57.6%), enterocele in seven (10.6%), and rectocele in three (4.5%). Defecography in women showed intussusception in 89 patients (44.9%), enterocele

Figure 2 Results of defecography with regard to rectocele, intussusception and enterocoele in men and women. Rectocele: $P < 0.001$, Enterocoele: $P < 0.005$, Intussusception: NS.

in 59 (29.8%), and rectocele in 88 (44.4%). There was a significantly higher proportion of rectocele and enterocoele in matched women (Figures 2 and 3). There was no statistically significant difference for the diagnosis of intussusception.

Distance between the pubococcygeal line and the anorectal junction at the three positions (rest, squeeze and strain) was significantly different between men and women, with a lower position of the perineum in women regardless of position ($P < 0.001$) (Figure 4). There was a greater incidence of perineal descent at rest in women compared with men ($P < 0.005$) (Figure 5). There was no difference between men and women for the diagnosis of perineal descent at straining.

DISCUSSION

Defecography is used commonly in women, but only a few procedures are carried out in men. In our department, men represented $< 10\%$ of all defecography procedures. To the best of our knowledge, no specific study of defecography has been carried out to explore the gender difference in the diagnosis of defecographic abnormalities. The pairing of our case-matched study was done for age and symptoms, with one man for three matched women, as is usual in this type of study. It allowed us to establish any sex difference in the prevalence of defecographic abnormalities.

Intussusception is very common in both sexes

Figure 3 Dynamic imaging during evacuation showed an enterocele (black arrow) associated with a rectocele (white arrow).

Figure 4 Distance between the pubococcygeal line and the anorectal junction at rest, squeeze and strain in men and women. $P < 0.001$.

Figure 5 Percentage of men and women with perineal descent at rest. $P < 0.005$.

(approximately half of patients undergoing defecography)^[7,8]. We did not observe any sex difference in prevalence. Enterocoele and rectocele were more common in matched women. This could be explained by obstetrical anteriority (vaginal delivery or hysterectomy). The consequences of obstetric damage on the perineum are well known^[18,19]. Enterocoele is also more frequent after hysterectomy^[20]. Rectocele is diagnosed 10 times more frequently in women, and appears to be characteristic of the female population. Rectocele has been reported previously as being uncommon in men^[15]. Chen *et al*^[15] have reported a prevalence higher than ours (17% *vs* 4.4%), and a frequent association between rectocele and prostatectomy (40%). We did not assess the history of all patients, but this difference could be explained by the higher mean age of the patients in the study of Chen *et al*^[15] (72.4 years) than in our study (55.4 years), because prostatectomy is more likely in older patients.

The distance between the pubococcygeal line and the

anorectal junction, which determines the position of the perineum, was greater in women for the three positions (rest, squeeze and strain). As a consequence, there was a gender difference for the diagnosis of perineal descent at rest. There was no such difference for perineal descent at straining. This raises the question that the normal level of the perineum could be different in both sexes. However, our study concerned only symptomatic patients and this needs to be investigated in control subjects. No sex-related definition of pelvic floor disorders was established, therefore, our diagnostic criteria were those commonly used, which means those used in women. However, new criteria for the diagnosis of perineal descent at rest in men could probably be defined. The same question can also be raised in elderly patients, for whom diagnostic criteria could also be adapted^[21].

Determination of the clinical value of defecographic abnormalities is also difficult and remains a subject of debate^[22-26]. Defecographic abnormalities have been shown not to be symptom-related^[12]. This study confirmed this finding, because there were gender differences among symptom-matched patients. Interpretation should be cautious because radiographic changes can be demonstrated in healthy subjects of various ages^[27,28]. Interobserver agreement is good for rectocele and enterocele^[29] but appears insufficient for perineal descent^[25]. Different methods for measuring parameters, especially perineal descent, have been described, with controversy as to which is the most accurate, and with little agreement^[26,30,31]. New examinations are also possible, such as magnetic resonance defecography, to assess pelvic floor disorders^[32,33].

In conclusion, defecography is a potential adjunct to clinical evaluation of men with constipation, fecal incontinence or pelvic pain. With symptoms equal, some defecographic abnormalities are sex-related: rectocele, enterocele and perineal descent at rest were observed less frequently in men.

COMMENTS

Background

Posterior pelvic floor disorders are caused by changes in the musculo-aponeurotic support of the pelvic floor. Defecography (radiographic dynamic rectal examination) provides precise information on anorectal and pelvic floor functions for patients with constipation, fecal incontinence and pelvic pain. These symptoms are more frequent in women, and some are related to obstetrical consequences. Little is known about the influence of gender in patients with pelvic floor disorders.

Research frontiers

Radiological exploration of pelvic floor disorders is important to elucidate the pathophysiology and assist in deciding the therapeutic strategy. It is difficult to attribute a radiological abnormality as the direct cause of the symptoms. A better knowledge of gender difference in the prevalence of defecographic abnormalities appears to be useful.

Innovations and breakthroughs

To the best of the authors' knowledge, no specific study of defecography has been carried out to explore the gender difference in the diagnosis of defecographic abnormalities. The strength of this study was that it assessed gender in the diagnosis of defecographic abnormalities.

Applications

For the same complaint, defecographic abnormalities are different in men than

in women: rectocele, enterocele and perineal descent at rest were less frequent in men than in women. Discussion of sex differences in pelvic floor disorders could probably help to assess more precisely these nosological entities. New examinations are also possible, such as magnetic resonance defecography.

Terminology

There are several defecographic abnormalities. Rectocele is an outpouching of the anterior rectal wall. Enterocele is a herniation of the small bowel between the vagina and rectum. Perineal descent is an abnormal position of the perineum under the pubococcygeal line.

Peer review

The results of this study are interesting, although the method of this study (defecography) is relatively old and slightly controversial. The results of this study raise issue concerning gender differences in pelvic floor disorders, and may bring a new dimension.
