ABOUT COVER

Editorial board member of *World Journal of Gastroenterology*, Maurizio Degiuli, FRCS (Gen Surg), MD, PhD, Associate Professor, Head, Department of Oncology, University of Turin, School of Medicine, San Luigi University Hospital, Orbassano- Turin 10043, Italy

AIMS AND SCOPE

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a peer-reviewed open access journal. *WJG* was established on October 1, 1995. It is published weekly on the 7th, 14th, 21st, and 28th each month. The *WJG* Editorial Board consists of 1375 experts in gastroenterology and hepatology from 68 countries.

The primary task of *WJG* is to rapidly publish high-quality original articles, reviews, and commentaries in the fields of gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, hepatobiliary surgery, gastrointestinal oncology, gastrointestinal radiation oncology, gastrointestinal imaging, gastrointestinal interventional therapy, gastrointestinal infectious diseases, gastrointestinal pharmacology, gastrointestinal pathophysiology, gastrointestinal pathology, evidence-based medicine in gastroenterology, pancreatology, gastrointestinal laboratory medicine, gastrointestinal molecular biology, gastrointestinal immunology, gastrointestinal microbiology, gastrointestinal genetics, gastrointestinal translational medicine, gastrointestinal diagnostics, and gastrointestinal therapeutics. *WJG* is dedicated to become an influential and prestigious journal in gastroenterology and hepatology, to promote the development of above disciplines, and to improve the diagnostic and therapeutic skill and expertise of clinicians.

INDEXING/ABSTRACTING

World Journal of Gastroenterology (*WJG*) is now indexed in Current Contents[®]/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch[®]), Journal Citation Reports[®], Index Medicus, MEDLINE, PubMed, PubMed Central, Digital Object Identifier, and Directory of Open Access Journals. The 2015 edition of Journal Citation Reports[®] released by Thomson Reuters (ISI) cites the 2015 impact factor for *WJG* as 2.787 (5-year impact factor: 2.848), ranking *WJG* as 38 among 78 journals in gastroenterology and hepatology (quartile in category Q2).

Abstract

Immune checkpoint inhibitors represent revolutionary
anti-cancer agents, being rapidly approved in different
malignancies and settings. Gastrointestinal (GI) cancers

represent a wide variety of tumors with specific
characteristics and different responses to various
therapeutic alternatives; while some are chemo-
sensitive others are chemo-resistant and only respond
to more aggressive cytotoxic regimens, targeted
therapies or a combination of both. Preliminary results
of immune checkpoint inhibitors in some GI cancers are
promising, namely in hepatocellular carcinoma, anal
cancers and microsatellite instability high colorectal
cancers. An impressive instead of a impressive number
of immune checkpoint inhibitors are being evaluated in
different indications in GI cancers as single agents or
in combination with other agents. We reported in this
paper ongoing and published trials evaluating immune
checkpoint inhibitors in hepatocellular carcinoma and
biliary tract cancers, esophageal, gastric, pancreatic,
colorectal and anal cancers and we discussed the future
perspectives of these agents in GI cancers.

Key words: Immunotherapies; Cancers; Digestive;
Checkpoint inhibitors; Gastrointestinal

Core tip: Immune checkpoint inhibitors represent new
promising anti-cancer therapies, rapidly approved
in different malignancies and settings. We aimed in
this editorial to report all the ongoing and published
trials evaluating these agents in gastro-intestinal
malignancies, to focus on the past expectations and the
reality of the results and finally, to discuss the future
perspectives of these agents in this field.

INTRODUCTION

Since the emergence of immune checkpoint inhibitors (ICI) in the last few years, hundreds of trials have been attempting to test their efficacy in the treatment of various malignancies and in different settings^[1]. Melanomas, non-small cell lung cancer (NSCLC), renal cell carcinomas and bladder cancer are the three malignancies, where these agents have presently gained approval, mainly in metastatic as first line treatment in melanomas and in the second line setting for the three others^[2-5]. Most importantly, one of these agents, ipilimumab, has been approved in the adjuvant setting for the treatment of melanoma^[6].

Similar response rates (RR) have been reported in different malignancies ranging between 15% to 25%, except for sarcomas, colorectal cancers (CRC), pancreatic, breast and prostate cancers, where efficacy has not been demonstrated or is still under evaluation in clinical trials. Preliminary results from phase 1 and 2 trials are reporting response rates between 15% to 25% in esophageal, gastric, hepato-biliary and anal cancer, similar to those described in other malignancies. Two exceptions in gastrointestinal (GI) cancers are pancreatic and CRC. In pancreatic cancer, we still do not have any preliminary results from trials looking into anti-PD1 agents and those evaluating anti-CTLA4 agent were mostly disappointing^[7]. After several trials failed to demonstrate the value of ICI in CRC, it was initially believed that these agents would not easily find their way into the preexisting therapeutic arsenal. It was only after one patient with MMR-deficient CRC demonstrated a spectacular response to anti-PD1 agent that a potential predictive biomarker was brought to light. Effectively, the RR in this subgroup of patients exceeded 40%^[8].

Despite the promising results in GI malignancies, ICI have not yet been approved in any of the aforementioned tumors. Herein, we briefly summarize the results of select trial with results that might have an impact on our clinical practice in the foreseeable future (Table 1).

CHECKPOINT INHIBITORS RESULTS IN GI CANCERS

Esophageal cancer

Results from two phase II trials evaluating nivolumab and pembrolizumab in esophageal cancers demonstrated an acceptable safety profile, meaningful clinical activity and RR of around 20% in heavily pretreated patients^[9]. Nivolumab is evaluated in squamous cell carcinoma regardless of PD-L1 status, while pembrolizumab is mainly being tested in patients with squamous cell carcinoma (77%), but PD-L1 positivity was set as an inclusion criteria^[10].

Gastric cancer

In gastric adenocarcinomas, tremelimumab (anti-

CTLA4) showed a response rate of 5% in a phase I trial^[11]. A phase II trial testing nivolumab in pretreated metastatic adenocarcinoma of the stomach and the gastroesophageal junction reported response rates around 12%, independently of the PD-L1 status^[12], while a phase I b trial evaluating pembrolizumab in pretreated metastatic adenocarcinoma of the stomach and the junction showed response rates exceeding the 30% in PD-L1 positive patients^[13]. In ASCO 2016, a trial tested avelumab as second line treatment and as maintenance treatment of advanced gastric or gastro-esophageal junction, the RR in second line setting was 18% in PD-L1 positive tumors and 9% in PD-L1 negative tumors; the disease control rate (DCR) was 29%^[14]. The combination of ipilimumab and nivolumab was tested at two different doses in phase I / II trial in gastric or gastro-esophageal adenocarcinoma, progressing after chemotherapy; the RR was 26% with the combination of nivolumab 1 mg/kg and ipilimumab 3 mg/kg and 14% with nivolumab^[15].

Pancreatic

A phase II trial evaluating ipilimumab in pancreatic cancer failed to discern any clinical activity as no response were reported in any of the 26 patients (0%)^[7]. Moreover, we do not have any preliminary results with anti-PD1 agents; three ongoing trials are evaluating nivolumab as single agent, nivolumab in combination with ipilimumab and nivolumab in combination with gemcitabine, which might act as a stimulant for neo-antigen expression.

Hepatocellular and biliary tract carcinoma

The safety profile and antitumor activity of tremelimumab, in patients with hepatitis-C-induced liver cirrhosis and subsequent advanced hepatocellular carcinoma (HCC), was promising with RR of approximately 17% and stable disease of 76%^[16]. Additionally, Nivolumab was tested in patients with sorafenib-refractory or sorafenib-intolerant HCC regardless of hepatitis status. Preliminary results were promising with RR of 23% (15% in uninfected and 32% in infected HCC)^[17]. Not only do these trials highlight the efficacy of ICI in this subset of patients, but they also provide valuable information in regards to the potential use of immunotherapy in patients with less than vigorous liver function. An ongoing trial randomized, multicenter, phase III study is comparing nivolumab to sorafenib in first-line treatment in patients with advanced hepatocellular carcinoma (NCT02576509).

Pembrolizumab was also tested in pretreated, PD-L1 positive, adenocarcinoma of the gallbladder and biliary tract - excluding ampullary carcinomas - with promising results; RR of 17% and SD of 17%^[18].

CRC

As previously mentioned, various phase I trials of anti-CTLA4 or anti-PD1 agents in CRC came to naught,

Table 1 Summarizes publish and ongoing clinical trials evaluating checkpoint inhibitors in gastrointestinal cancers

Ref.	Phase/ <i>n</i>	Agent	Histology distribution	Chemotherapies	ORR	SD	OS
Esophageal cancer							
Kojima <i>et al</i> ^[9] , 2016	II / 65	Nivolumab	100% squamous	Median prior regimen 3	17.20%	25%	12.1

Anal cancer							
Ott <i>et al</i> ^[22] , 2015	I b / 25	Pembrolizumab	Refractory metastatic squamous cell carcinoma of the anal canal	Prior systemic therapies	20%	40%	NA
Morris <i>et al</i> ^[23] , 2016	II / 39	Nivolumab	Refractory metastatic squamous cell carcinoma of the anal canal	Previously treated, immunotherapy naïve	21%	58%	NA

ORR: Objective response rate; OS: Overall survival; MMR: Mismatch repair; NR: Not reached; NA: Not available.

even in patients with PD-L1 positive tumors^[19-21]. Only one heavily pretreated patient presented a remarkable response to nivolumab and this patient was later found to harbour a MMR-deficient CRC. As such, one phase II study demonstrated significant RR (40%) in MMR-deficient CRC patients versus 0% in MMR proficient CRC patients treated with pembrolizumab^[8]. Therefore, MMR status is now believed to be a valuable predictor of response to anti-PD1 agents, even more valuable than PD-L1 status for that matter. This finding also extends beyond CRC as it highlights the importance

of mutational burden as a predictor to ICI response since patients with MMR deficient malignancies tend to have higher rates of intra-tumoral mutations and a subsequent expression of cell surface neo-antigens leading to a more potent immune response.

Anal cancer

A phase I b trial evaluating pembrolizumab in pretreated squamous cell anal cancer showed response rates of 20% and a stable disease in 40% of patients PDL1 positive tumors^[22]. A multi-institutional eETCTN phase II

study of nivolumab in refractory metastatic squamous cell carcinoma of the anal canal was presented in ASCO 2016 including 37 patients, some of them carrying HIV or hepatitis B or C. The results showed RR of 21% and DCR of 70%; it was not reported more severe adverse events in HIV positive patients^[23].

FUTURE PERSPECTIVES

With the express approval of checkpoint inhibitors in different malignancies, these agents will most likely be gain approval for the treatment of some GI malignancies in the very near future.

Anti-CTLA4 agents are unlikely to yield substantial value in the treatment of GI cancers, especially as single agents, because of lacking clinical activity, except of tremelimumab in HCV-induced HCC.

Anti-PD1 agents will soon be considered for the second line treatment of metastatic squamous cell carcinoma of the oesophagus, metastatic gastric adenocarcinoma and advanced cholangiocarcinoma after standard platinum-based therapy. The new molecular classification of gastric adenocarcinoma will help better define patients that might benefit from these therapies, mainly those expressing PDL1 and EBV positive gastric adenocarcinomas. Anti-PD1 agents will also be considered as second line treatment in advanced HCC while viral hepatitis status should be considered as a predictive biomarker for response since it clearly does not prevent the use of ICI.

Moreover, anti-PD1 agents will most likely be approved MMR-deficient CRC, which represent 10% to 15% of these tumors. Second line treatment of metastatic anal squamous cell carcinoma will also benefit from the emergence of these new agents after standard therapy, and HPV status should be looked into as a predictive biomarker.

With the increasing popularity of chemo-immunotherapy, it is also likely that such combinations will soon emerge and hasten the approval process in first line settings^[24].
