### ABOUT COVER

Editorial board member of *World Journal of Gastroenterology*, Maurizio Degiuli, FRCS (Gen Surg), MD, PhD, Associate Professor, Head, Department of Oncology, University of Turin, School of Medicine, San Luigi University Hospital, Orbassano- Turin 10043, Italy

### AIMS AND SCOPE

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a peer-reviewed open access journal. *WJG* was established on October 1, 1995. It is published weekly on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup>, and 28<sup>th</sup> each month. The *WJG* Editorial Board consists of 1375 experts in gastroenterology and hepatology from 68 countries.

The primary task of *WJG* is to rapidly publish high-quality original articles, reviews, and commentaries in the fields of gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, hepatobiliary surgery, gastrointestinal oncology, gastrointestinal radiation oncology, gastrointestinal imaging, gastrointestinal interventional therapy, gastrointestinal infectious diseases, gastrointestinal pharmacology, gastrointestinal pathophysiology, gastrointestinal pathology, evidence-based medicine in gastroenterology, pancreatology, gastrointestinal laboratory medicine, gastrointestinal molecular biology, gastrointestinal immunology, gastrointestinal microbiology, gastrointestinal genetics, gastrointestinal translational medicine, gastrointestinal diagnostics, and gastrointestinal therapeutics. *WJG* is dedicated to become an influential and prestigious journal in gastroenterology and hepatology, to promote the development of above disciplines, and to improve the diagnostic and therapeutic skill and expertise of clinicians.

### INDEXING/ABSTRACTING

*World Journal of Gastroenterology* (*WJG*) is now indexed in Current Contents<sup>®</sup>/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch<sup>®</sup>), Journal Citation Reports<sup>®</sup>, Index Medicus, MEDLINE, PubMed, PubMed Central, Digital Object Identifier, and Directory of Open Access Journals. The 2015 edition of Journal Citation Reports<sup>®</sup> released by Thomson Reuters (ISI) cites the 2015 impact factor for *WJG* as 2.787 (5-year impact factor: 2.848), ranking *WJG* as 38 among 78 journals in gastroenterology and hepatology (quartile in category Q2).

### Abstract

Colonic polyps may arise from BRAF inhibitor treatment of melanoma, possibly due to paradoxical activation of the mitogen-activated protein (MAP)-kinase pathway. In an alternative evidence based scenario, tubular colonic adenomas with *APC* gene mutations have also been identified in the context of BRAF inhibitor treatment, in the absence of mutations of *MAPK* genes. A minority of colorectal cancers develop by an alternative "serrated polyp pathway". This article postulates a novel hypothesis, that the established phenotypic and molecular characteristics of serrated colonic polyps/CRC offer an intriguing insight into the pathobiology of BRAF inhibitor induced colonic polyps. Serrated polyps are characterized by a CpG island methylation phenotype, *MLH1* silencing and cellular senescence. They also have *BRAF* mutations. The contention is that BRAF inhibitor induced polyps mimic the afore-described histology and molecular features of serrated polyps with the exception that instead of the presence of *BRAF* mutations they induce C-RAF homodimers and B-RAF: C-RAF heterodimers.

**Key words:** BRAF inhibitors; Malignant melanoma; Serrated polyps; Colonic polyps

**Core tip:** In this article, we focus on BRAF inhibitors, and their relationship to colonic polyps. As is already known, colonic polyps may arise from BRAF inhibitor treatment of melanoma, possibly due to paradoxical activation of the mitogen-activated protein-kinase pathway. In this article, we postulate a novel

hypothesis, that the established phenotypic and molecular characteristics of serrated colonic polyps offer an intriguing insight into the pathobiology of BRAF inhibitor induced colonic polyps.

BRAF inhibitor treatment of melanoma causing colonic polyps: An alternative hypothesis. *World J Gastroenterol* 2017; 23(17): 3022-3029 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v23/i17/3022.htm> DOI: <http://dx.doi.org/10.3748/wjg.v23.i17.3022>

## INTRODUCTION

Classically, 70%-75% of colorectal cancers (CRCs) arise through the adenoma-carcinoma sequence<sup>[1]</sup>. Inactivation of *APC* is the initial molecular change with subsequent alterations including *KRAS* mutation, Chr. 18q loss (*DCC* and *DPC4*) and subsequent inactivation of *TP53*<sup>[2,3]</sup>. An alternative route to colorectal cancer development is the "serrated polyp pathway". This is characterized by *BRAF* mutations, a CpG island methylation phenotype (CIMP), and cellular senescence. This distinct tumor subgroup accounts for 7.5% of all CRC and 17.5% of proximal CRC<sup>[4-6]</sup>.

Of all cases of metastatic CRC, 10% have *BRAF* mutations, with 95% of *BRAF* missense mutations causing amino acid substitutions at V600 in the expressed protein<sup>[7,8]</sup>. The hypothesis is that BRAF inhibitor treatment of melanoma will not cause "serrated polyp pathway" lesions per se, but by molecular mimicry, creates lesions with the clinical and molecular features of serrated lesions. The only difference is that these polyps will not have *BRAF* mutations but C-RAF homodimers and C-RAF: B-RAF heterodimers.

At the time of writing this manuscript a publication emerged evaluating multiple gastrointestinal polyps in patients treated with BRAF inhibitors<sup>[9]</sup>. Fourteen patients treated with BRAF inhibitors had endoscopic assessment for polyps. All patients that were treated with BRAF inhibitors for greater than 2 years, and who were in excess of 40 years of age, had colonic tubular adenomas. Hyperplastic polyps were also identified and the temporal evolution of polyps was suggestive of a causal association with BRAF inhibition. Next generation sequencing of the polyps did not identify mutations within MAPK pathway genes but did identify *APC* mutations in all tubular adenomas. This was most commonly a truncating mutation in the  $\beta$ -catenin binding domain (R1450X). In an *Apc* Min +/- mouse model there was an increased number of polyps compared to controls (20.8 vs 12.8,  $P = 0.016$ ) respectively.

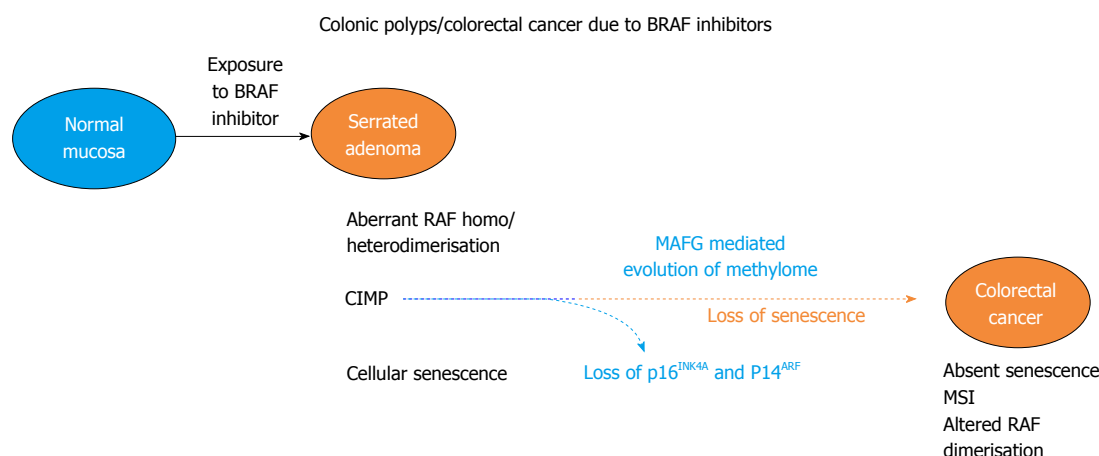

Altered stochastic relations in RAF dimers and epigenetic changes form an important part of our contention that some BRAF inhibitor induced polyps arise *via* the serrated polyp pathway. Epigenetics affects

gene expression without altering the DNA nucleotide sequence. Next generation sequencing would fail to detect such changes. In addition, nuclear  $\beta$ -catenin was perhaps unexpectedly not detected in the human colonic polyps. The contention is that these findings of a possible role for the classical adeno- to carcinoma sequence does not exclude the possibility that corruption, or molecular mimicry of the serrated polyp pathway may account for some BRAF inhibitor induced polyps.

The "serrated polyp pathway" is vicariously informative of a subgroup of colorectal cancers in which MAP-kinase activation is important, as exemplified by their molecular signature with characteristic *BRAF* mutants. This informs of a molecular circumstance in which RAF is dysregulated in colonic polyps. Paradoxical BRAF activation and upregulation of MAP-kinase signaling, is due to RAF inhibitors trans activating RAF dimers with increased ERK signaling in cells, which are BRAF wild-type<sup>[10]</sup>. There is preclinical evidence in other tumor types that RAF inhibitors increase MAP kinase pathway activity by inducing C-RAF heterodimers or B-RAF homodimers<sup>[10-12]</sup>.

Clinically this molecular phenomenon is only brought to phenotypic manifestation in specific circumstances. Most phenomenon described so far have been in the context of pre-existing "primed *NRAS*" mutations in keratinocytes causing cutaneous squamous cell carcinomas, or the interesting case of progression of a *RAS*-mutant leukemia during treatment with a RAF inhibitor<sup>[13]</sup>. A case has also been described of a new *RAS*-mutant pancreatic adenocarcinoma in a patient receiving combined BRAF and MEK inhibitor treatment for metastatic melanoma<sup>[14]</sup>. The first described premalignant colonic adenomas and gastric polyps associated with inhibition of BRAF were reported in 2012<sup>[15]</sup>. Four of eight patients with V600E mutant metastatic melanoma on BRAF inhibitor treatment greater than 2 years had a colonoscopy. Three of the four patients were found to have multiple colonic adenomas and two had hyperplastic polyps. One of these patients had a negative colonoscopy five months prior to initiation of Vemurafenib, but at colonoscopy four colonic adenomas and one hyperplastic polyp were identified.

The postulate in this article is that colonic polyps may arise due to BRAF inhibitors because of altered gene expression due to epigenetic dysregulation of the methylome. Implicated genes need to be further delineated. In a simple comparator example the tumor suppressor, and RAS domain family member, *RASSF1A* undergoes hypermethylation in thyroid cancer with an activating mutation of *BRAF* gene<sup>[16]</sup>. *RASSF1A* is also methylated in CIMP CRC and its methylation is correlated with CRC liver metastasis<sup>[17]</sup>. Also unlike the static pre-primed *RAS* mutant models the CpG island methylated gene profile is one of temporal evolution, mediated by BRAF and changes with progression along the serrated polyp pathway. An adenoma to carcinoma progression model with tumors arising in the context

**Figure 1** Treatment with BRAF inhibitors may lead to colonic adenomas mimicking serrated adenomas with characteristics of cellular senescence, CpG island methylation phenotype, but with *BRAF* mutations instead substituted by altered RAF homo and hetero dimers. Later selective gene silencing can cause loss of senescence and progression to colorectal cancer. CIMP: CpG island methylation phenotype.

of BRAF inhibitor induction is illustrated in Figure 1.

## MOLECULAR BIOLOGY OF SERRATED POLYPS

The World Health Organization classifies serrated polyps into 3 subtypes: hyperplastic polyps, sessile serrated adenomas, and traditional serrated adenomas. The terms serrated polyps and serrated adenomas are synonymous. Serrated CRC simply is a histologic descriptor of a sawtooth-like infolding of the intestinal lesion epithelium. In one series they accounted for 30% of colorectal cancers, and they arise from serrated polyps *via* the “serrated polyp pathway”<sup>[18]</sup>. Serrated tumors can also be sub-categorized using molecular descriptors. These are: (1) *KRAS* mutant, CIMP-low, MSS/MSI-low (microsatellite stable/microsatellite instability-low); (2) *BRAF* mutant, CIMP-high, MSI-high; and (3) *BRAF* mutant, CIMP-low, MSS/MSI-low.

Silencing of *MLH1* by CpG island promoter methylation causes microsatellite instability and a hyper mutable phenotype, as it is a mismatch repair gene. Serrated polyps have a co-association with gastric metaplasia. Using the aberrant CpG island methylation phenotype as a categorical arbiter, colorectal cancers can be sub-divided into CIMP-high (CIMP-1), CIMP-low (CIMP-2), and CIMP negative (CIMP-3)<sup>[19,20]</sup>. The *BRAF* mutation, *MLH1* methylation and CpG island methylation phenotype describes an aggressive subgroup of colorectal cancer.

A study led by Fred Hutchinson Cancer Research Center, WA, assessed the *BRAF* mutant, *MLH1* silenced, CIMP, molecular signature in a series of polyps. Participants underwent an initial index colonoscopy for any indication. There were 580 conventional adenomas and 419 serrated lesions identified. CIMP methylation was determined by assessing methylation status of the following genes: *IGF2*, *NEUROG1*, *CACNA1G*,

*RUNX3*, and *SOCS1*<sup>[21]</sup>. The prevalence of the mutations leading to *BRAF* V600E, *MLH1* methylation and CIMP in the adenomas was < 1%. In contrast, 55% of serrated lesions had mutations leading to *BRAF* V600E, 5% had *MLH1* methylation and 26% were CIMP-high. The highest prevalence of these markers occurred within the sessile-serrated polyps. Sessile serrated polyps were *BRAF* mutant in 68%, *MLH1* methylated 11%, and CIMP-high 49%. In a series of sporadic classical serrated adenomas the promoter of *SLC5A8* was methylated in 82.5%<sup>[22]</sup>. The extent of widespread aberrant CpG island methylation increased with histological progression of serrated adenomas. Methylation of genes encoding p14, p16, MGMT, FHIT, and TIMP3 were found to be important tumorigenic steps in the serrated neoplastic pathway. A longitudinal study, which evaluated patients with sessile serrated polyps, demonstrated that 12.5% developed colorectal cancer within 5 years<sup>[23]</sup>. Metastatic *BRAF* mutant colorectal cancer have a particularly poor prognosis with a median overall survival of 20 mo compared to 47 mo for those which are *BRAF* wildtype<sup>[24]</sup>.

A simple analogy remains however with previously primed *NRAS* mutant colonic epithelium but the frequency of this mutation is low. An inverse relationship also exists for *KRAS* and *BRAF* mutations in serrated adenomas<sup>[25]</sup>. Though the theme of histopathology and molecular mimicry of serrated colonic lesions suffuses this hypothesis article, BRAF inhibitors may also be relevant to progression of *KRAS* mutant adenomas to carcinoma by removal of the senescence barrier to developing cancer. Expression of oncogenic K-ras<sup>G12D</sup> in mice induces serrated hyperplasia with overexpression of p16<sup>ink4a</sup> and induction of senescence<sup>[26]</sup>. When Ink4a/Arf is deleted in K-ras<sup>G12D</sup> expressing mice senescence is prevented with consequent invasion and metastasis as well as molecular and morphologic changes consistent with *KRAS* mutated serrated tumors. The reader is reminded that *CDKN2A* the gene that encodes p14 and

p16 is a participant gene of the CpG island methylated phenotype.

## MAFG AND ITS CO-REPRESSORS

This paper postulates that colonic polyps arising from BRAF inhibitor treatment are due to paradoxical MAP-kinase upregulation. However, the exact molecular mechanism of how this causes colonic polyps has been elusive. A conceptual advance may be inferred from findings by investigators at Howard Hughes Medical Institute and the University of Massachusetts, MA<sup>[27]</sup>. Aberrant CpG island methylation of *MLH1*, was selected as a prototypical epigenetic gene dysregulation event, with silencing of *MLH1* in CIMP-1 colorectal cancer. This gene is a member of the CIMP gene spectrum, which characterizes a subset of CRC. Using an RNAi screen the transcriptional repressor MAFG (v-maf avian musculoaponeurotic fibrosarcoma oncogene homolog G) was established as a decisive requirement for *MLH1* silencing and establishing the CpG island methylation phenotype of BRAF (V600E) colorectal cancer. In *BRAF* mutant colorectal cancer cell lines MAFG bound to the promoter of *MLH1* as well as other CIMP genes with recruitment of a co-repressor complex including its' heterodimeric partner BACH1, the DNA methyltransferase DNMT3B and the chromatin remodelling factor CHD8. This caused hypermethylation and transcriptional silencing. In a *BRAF* mutant cell line, treatment with a BRAF inhibitor decreased MAFG protein. Not all genes of CIMP co-associate with mutant *BRAF* in individual serrated colonic lesions. An inference could be drawn that in *BRAF* mutant sporadic colonic lesions with co-association of CIMP, BRAF inhibitors could de-repress genes within the CIMP phenotype in a binary way.

There is the alternative scenario of patients developing iatrogenic colonic polyps from exposure to BRAF inhibitors indicated for treating melanoma. In *BRAF* wild type colonic epithelium, BRAF inhibitors could, through C-RAF homodimers or C-RAF: B-RAF heterodimers, upregulate BRAF-MEK-ERK activity. Upregulation of this pathway leads to ERK1 phosphorylation of S124 of MAFG with increased MAFG stability and protein levels. There is consequential MAFG binding to DNA with transcriptional silencing of genes possibly replicating the CIMP gene signature. MAFG levels are also increased by prevention of polyubiquitination and proteosomal destruction.

Representative genes of CIMP gene promoters in CRC include *DAPK1*, *PRDM2*, *AOX1*, *CACNA1G*, *CHFR*, *EFEMP1*, *HAND1*, *IRF8*, *LOX* and *p16INK4A*. PAT-ChIP analysis of MAFG binding to these 10 representative CIMP genes' promoters, and adjacent normal tissue, in BRAF mutant colorectal cancers demonstrated that MAFG was substantially enriched compared to matched normal tissue. In another study DNA methylation of 16 CpG islands in 904 colorectal cancers was quantitated<sup>[28]</sup>. The 5 markers (SOCS1, IGF2,

NEUROG1, RUNX3 and CACNA1G), CDKN2A, MINT31, CRABP1, MLH1, p14 and WRN usually clustered on unsupervised hierarchical clustering analysis. These co clustered with microsatellite instability and mutant *BRAF*. Multivariate logistic regression analysis found CIMP-high to be independently associated with proximal tumor location, older age, MSI- high, poor differentiation, BRAF mutation, and inversely with CTNNB1 and LINE-1 hypo-methylation. p53-negativity, signet ring cells and mucinous histology only co-associated with CIMP on univariate analysis. BRAF inhibitors paradoxically trans activate RAF dimers and this is the mechanism for paradoxical MAP-kinase up regulation in BRAF wild type cells. This is mediated by drug binding to the ATP-binding site of one kinase of the RAF dimer C-RAF: C-RAF or CRAF: BRAF. Inhibition of one promoter leads to transactivation of the drug-free promoter<sup>[10]</sup>.

## EPIGENETICALLY DEREGULATED CIMP GENES: INITIAL SUSPECTS

Epigenetic alterations are heritable changes in gene expression in the absence of changes in the DNA sequence. They usually are secondary to methylation of DNA in gene promoter regions or modifications in histone acetylation. Aberrant DNA methylation can consist of either site-specific hypermethylation of DNA or global hypomethylation of DNA. One example of hypomethylation in CRC is the gene *LINE-1*. *LINE-1* hypomethylation in CRC is associated with inferior survival, with a hazard ratio of 2.45 in MSI-high cancers<sup>[29]</sup>. Widespread hypermethylation of CpG islands is described as the CpG island methylation phenotype. *CDKN2A* is a member gene of the CpG island methylation phenotype of the serrated pathway and its transcription is silenced in a subset of serrated polyps. In an interesting comparator, *CDKN2A* is also silenced in a minority of melanomas with loss of p16<sup>INK4A</sup> causing de-repression of cyclin D - CDK4/6. Selected panel genes of the CIMP profile in CRC are detailed in Table 1 below, however these only represent a small proportion of the probable 100 s-1000 s of methylated CIMP genes. This CIMP-gene panel in Table 1 was supplemented by selected other genes in one study in 2013<sup>[30]</sup>. Additional genes of potential relevance identified then included *RASSF1A*, *APC*, *PTEN* and *TWIST1*. The methylome of 100s to 1000s of genes remains to be further interrogated to establish the genes of greatest importance in BRAF inhibitor induced colonic polyps.

BRAF inhibitor treatment decreases MAFG protein in *BRAF* mutant CRC cells, whereas BRAF inhibitor treatment has been demonstrated to paradoxically increase MAP-kinase activity in BRAF wild type keratinocytes with pre-primed RAS mutations. Therefore the effects are context dependent but ultimately will alter the spectrum of repressed and expressed genes,

in some circumstances epigenetically.

Some genes are deserving of some further detail however acknowledging the limitations of current knowledge. The INK4a/ARF locus on Chromosome 9p21 encodes both p16<sup>INK4a</sup> and p14<sup>ARF</sup>. Despite these tumor suppressor genes sharing exons, their encoded proteins do not have amino acid homology. This is because of differences in their reading frames. Progression of sessile serrated adenomas to CRC is restrained by p16<sup>INK4a</sup> mediated senescence as well as by p53, a downstream effector of p14<sup>ARF</sup>. p16<sup>INK4a</sup> and p14<sup>ARF</sup> are frequently inactivated in CRC by aberrant promoter methylation of their encoding gene *CDKN2A*<sup>[31]</sup>. In a tumor progression model paradoxical MAP-kinase mediated loss of oncogene induced senescence was found to be attributable to functional loss of p16<sup>INK4a</sup>. Removal of the senescence barrier permits progression to colon cancer.

Genes specifically methylated by mutant BRAF in CRC have been identified<sup>[32]</sup>. These include forkhead box (*FOX*) transcription factors that associate with the PI3 kinase pathway, smoothened (part of the Hedgehog signaling pathway) and *MLH1*, as is illustrated in Table 2 below. The repressed expression of *FOXD3* in colorectal tumors has been attributed also to promoter hypermethylation<sup>[32]</sup>. The average CRC methylome comprises hundreds to thousands of genes but identification of the oncogenic drivers is difficult. p16<sup>INK4a</sup> is up and down regulated in a context dependent manner, with implications for loss of senescence, and would appear a likely culprit indirect repressor of *FOXD3*. In mammalian cells p16<sup>INK4a</sup> inhibits activity of cyclin D-CDK4/6 complexes. When

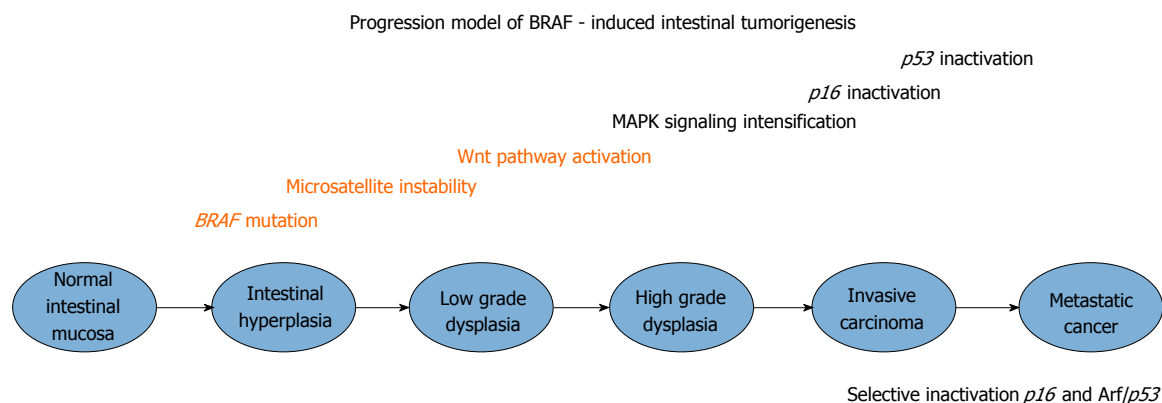

active these complexes phosphorylate and regulate the mammalian Forkhead Box transcription factor (*FOX*M1) which itself inhibits senescence. *FOX*M1 promotes the growth and metastasis of colon cancer cells in orthotopic mouse models<sup>[33]</sup>.

In a study of CRC cell lines for all CpG rich regions, 389 had co-occurrence of mutant BRAF and CIMP, 369 mutant BRAF alone and 360 CIMP alone<sup>[32]</sup>. When filtered using H3K27me binding within embryonic stem cells it was found that 96 had co-occurrence of mutant BRAF and CIMP, 90 had mutant BRAF alone and 112 CIMP alone. Pathways enriched for *BRAF* mutation associated promoter methylation once ES cell K3K27me binding promoter regions were excluded, and are detailed in Table 2. Considering just one selected gene, Cyclin D1 is commonly over activated in CRC. Preclinical studies found that Aspirin likely inhibits Cyclin D1/CDK4 in CRC cells through the p38 MAP-kinase pathway. This inhibition causes NF-κB mediated induction of nucleolar translocation of RelA (p65) -a component of NF-κB-, as well as apoptosis<sup>[34]</sup>. BRAF mutations correlate with Cyclin D1 overexpression in metastatic colorectal cancer<sup>[35]</sup>.

## CELLULAR SENEESCENCE

Hayflick and Moorhead first observed cellular senescence in 1961 in experiments where serial *in vitro* cultivation of human fibroblasts caused them to enter an irreversible state of arrested growth<sup>[36]</sup>. The eponymously named Hayflick factors that characterize senescence, record a cells or tissues proliferative history. These include telomere shortening, de-repression of the INK4a/ARF locus and accumulation of DNA damage. Senescence and p16<sup>INK4a</sup>/p14<sup>ARF</sup> are of particular interest as senescence is a characteristic feature of serrated polyps. As previously detailed, silencing of *CDKN2A* the gene encoding these tumor suppressors is part of the CpG island methylation phenotype. In a study of BRAF mutated colonic serrated lesions, p16<sup>INK4a</sup> was upregulated in premalignant lesions only to be later lost in invasive serrated carcinomas<sup>[37]</sup>. Progression of the malignant phenotype in serrated lesions was accompanied by increased methylation of the *CDKN2A* gene promoter. Simply stated, progression from adenoma to BRAF mutant CRC partly involves epigenetic loss of senescence. As a physiologic comparator, in development epigenetic regulators of the Polycomb family are partially responsible for low expression levels of p16<sup>INK4a</sup> and ARF<sup>[38,39]</sup>.

An experimental mouse model of *Braf*<sup>V600E</sup> induced intestinal carcinogenesis has been created and described, using a conditional Cre activated *Braf* knockin allele<sup>[40]</sup>. The inferred findings arising from this murine model are illustrated in Figure 2. Murine *Braf*<sup>V637E</sup> in exon 18 is orthologous to human *BRAF*<sup>V600E</sup> exon 15 mutations. One hundred percent of Villin-Cre;

**Figure 2** Murine  $\text{Braf}^{\text{V637E}}$  progression model of intestinal tumorigenesis via the alternative/serrated pathway illustrates the cumulative acquisition of molecular pathway derangement. Intensification of MAP kinase signaling and selective inactivation of genes that govern cellular senescence with progression is a pertinent inference. This figure is based on the model developed by Rad *et al*.<sup>[40]</sup>

$\text{Braf}^{\text{LSL-V673}}/+$  mice developed crypt hyperplasia (restricted to mid-upper intestinal crypts) without apoptosis. In a phenomenon determined by increasing age, hyperplasia progressed to dysplasia, and typical serrated adenomas but not sessile serrated adenomas. This may be because these mice models have a predilection for the development of small intestinal rather than colonic polyps, and sessile serrated adenomas usually only occur in the colon. Dysplasia progressed to carcinoma in 16% of  $\text{Braf}^{\text{V637E}}$  knockin mice. Intercross experiments to generate progeny were also undertaken using  $\text{Braf}^{\text{LSL-V637E}/+}; \text{p53}^{\text{LSL-R172H}}/+$  and  $\text{Vil-Cre}; \text{Braf}^{\text{LSL-V637E}/+}$  mice. These were performed because of the long latency for cancer formation and to assess the functional consequences of p53 inactivation. The arising progeny were  $\text{Villin-Cre}; \text{Braf}^{\text{V637E}/+}; \text{p53}^{\text{LSL-R172H}}/+$ . No comparator difference was found in the proportion of such progenitor mice developing serrated adenomas but invasive cancer were more frequent with the average number of cancers 5.2 times more frequent in the  $\text{Braf}^{\text{LSL-V637E}/+}; \text{p53}^{\text{LSL-R172H}}/+$  group ( $P = 0.007$ ; Mann-Whitney rank sum test). In the interval from 10-20 mo, 56% of compound mutant mice developed cancer. The inference is that p53 does not have an impact on early stages of BRAFV637E induced tumorigenesis, but is important in late stages including invasiveness. In the molecular progression from dysplasia to adenoma with subsequent carcinoma, selective pressure for p53 inactivation developed at more advanced stages of tumor evolution with p16 inactivation promoting advanced phases of  $\text{Braf}^{\text{V637E}}$  induced intestinal tumorigenesis.  $\text{P16}^{\text{Ink4a}}$  compound homozygous mutant mice had a 6.4-fold greater increase in carcinoma compared to mice with  $\text{p16}^{\text{Ink4a}}$  expression. The serrated cancer progression model discovered by Rad and colleagues is illustrated in Figure 2.

The described genetic progression model of  $\text{Braf}^{\text{V600E}}$ -intestinal tumorigenesis in mice demonstrates selective pressure for inactivation of the p16/Rb and Arf/p53 pathways late in the progression path. A paradoxical

increase in MAP-kinase activity would through C-RAF: B-RAF heterodimers and C-RAF homodimerisation cause MAFG mediated silencing of  $\text{p16}^{\text{Ink4a}}$  expression. This would have the effect of loss of senescence in later stages of progression from colonic polyps to CRC.

## FUTURE SCIENTIFIC INVESTIGATION TO CONFIRM THE HYPOTHESIS

A comprehensive compilation of a series of patients on BRAF inhibitor treatment for melanoma in whom colonic polyps arise is mandated. This will permit histological characterization as to whether these polyps are serrated or adenomatous. Bi-sulfite sequencing analysis of genes that are proposed to be epigenetically silenced by CpG island promoter methylation should inform on the relative merits of the epigenetic component of the iatrogenic disease model. DNA and RNA of the selected genes of interest are suggested. Lastly RNAi screening to assess the level of MAFG in these polyps, itself a silencer of  $\text{p16}^{\text{Ink4a}}$  should provide evidence supporting the senescent tenet of the hypothesis.

## CONCLUSION

The prospect of efficacious medical treatment of colorectal cancers arising from BRAF inhibitor induced polyps is appealing. Endoscopic removal of colonic polyps is the optimal initial intervention. However the emergent molecular biology in this theory, which needs future evidential substantiation, suggests some molecular treatment approaches. One potential treatment modality in development is ERK inhibitors, which can decrease ERK1 phosphorylation of MAFG. The exciting recent findings of Amaravadi and colleagues suggest a classical adeno-carcinoma cause for gastrointestinal polyps arising from BRAF inhibitor treatment. The postulated theory of corrupted molecular mimicry of the serrated polyp pathway detailed above is supplementary rather than contradictory and deserves experimental investigation.
