analyzed by  $^{13}\text{C}$ -urea breath test. Incidence rates of adverse events were evaluated by use of questionnaires.

**RESULTS:** By intention-to-treat (ITT) analysis, the eradication rate in the LACM7 group was 94.9%, which was significantly higher than the LAC7 group (68.3%,  $P < 0.001$ ). Per protocol analysis also showed a significantly higher eradication rate in the LACM7 group (98.3%) than the LAC7 group (73.2%,  $P < 0.001$ ). Nevertheless, the incidence of serious adverse events did not differ between the two groups (RR: 1.10, 95% CI: 0.70-1.73,  $P = 0.67$ ).

**CONCLUSION:** Seven day non-bismuth quadruple therapy (LACM7) was superior to standard 7-d triple therapy (LAC7) for first-line eradication.

Non-bismuth quadruple therapy for first-line *Helicobacter pylori* eradication: A randomized study in Japan. *World J Gastrointest Pharmacol Ther* 2012; 3(1): 1-6 Available from: URL: <http://www.wjgnet.com/2150-5349/full/v3/i1/1.htm> DOI: <http://dx.doi.org/10.4292/wjgpt.v3.i1.1>

### Abstract

**AIM:** To find the way to improve the eradication rate of first-line therapy in Japanese patients.

**METHODS:** We prospectively compared the effectiveness of 7-d quadruple therapy to standard 7 d triple therapy in Japanese patients infected with *Helicobacter pylori* (*H. pylori*). One hundred and nineteen patients were randomly assigned to receive 7-d non-bismuth quadruple therapy with lansoprazole, amoxicillin, clarithromycin and metronidazole (LACM7) or 7-d triple therapy with lansoprazole, amoxicillin and clarithromycin (LAC7). After three months, *H. pylori* status was

### INTRODUCTION

*Helicobacter pylori* (*H. pylori*) infection plays a crucial role in the pathogenesis of chronic atrophic gastritis and peptic ulcer. Moreover, it has been identified as one of the most important causes of gastric cancer and contributes to

cancer initiation and progression<sup>[1]</sup>. *H. pylori* is associated strongly with the development of intestinal-type gastric cancer and metachronous cancer after endoscopic resection therapy<sup>[2,3]</sup> and eradication should reduce the risk of developing gastric cancer<sup>[4,5]</sup>.

The recommended treatment for *H. pylori* is a proton pump inhibitor (PPI)-based triple therapy using PPI, amoxicillin and clarithromycin or metronidazole given twice daily and considerable data support the use of this treatment<sup>[5]</sup>. However, the eradication rate for standard triple therapy has declined in recent years despite being > 80% before 2000<sup>[6,7]</sup>. At present, patients who fail first-line therapy usually receive second-line therapy in Japan. However, a second course of eradication therapy increases the financial burden and is time-consuming<sup>[8]</sup>.

Many attempts have been made recently to improve the initial eradication rates of *H. pylori*. Some studies have suggested prolonging the eradication period or taking drugs four or more times daily, but that might reduce compliance<sup>[9,10]</sup>. In this study, to find a more effective regimen to complete *H. pylori* eradication in first-line therapy, we compared the effectiveness of 7 d quadruple therapy of lansoprazole, amoxicillin, clarithromycin and metronidazole (LACM7) to 7 d standard triple therapy with lansoprazole, amoxicillin and clarithromycin (LAC7) for *H. pylori* eradication.

## MATERIALS AND METHODS

### Patients

The present study was a randomized, prospective trial performed at the Institute for Adult Diseases, Asahi Life Foundation, Tokyo, Japan, between March 2007 and January 2009. Patients who were diagnosed with peptic ulcer or atrophic gastritis by endoscopic examinations were included this study. Exclusion criteria were as follows: (1) younger than 18 years; (2) allergy to antibiotics; (3) active peptic ulcer undergoing PPI treatment; (4) present malignancy or history of malignancy; (5) previous total or subtotal gastrectomy; (6) pregnancy or nursing; and (7) previous *H. pylori* eradication therapy.

One hundred and nineteen patients infected with *H. pylori* were enrolled in this study. Of those, 93 were men (78%) and 26 were women (22%), ranging in age from 26 to 79 years (mean age 61.4 years). Clinical characteristics are shown in Table 1.

This study was approved by the ethics committee of the Institute for Adult Diseases before the start of patient enrollment and was performed in accordance with the principles set forth in the Declaration of Helsinki. Informed consent was obtained from all patients.

### Study design

Diagnosis of peptic ulcer or atrophic gastritis was determined through endoscopic examination. At endoscopy, biopsy samples were taken from the greater curvature of the antrum for rapid urease test (Helicocheck; Otsuka Pharmaceuticals, Tokyo, Japan), culture or histological

**Table 1** Characteristics of patients

Characteristics	Treatment groups		P value
	LACM7 (n = 59)	LAC7 (n = 60)	
Age (mean) (yr)	63 ± 8.7	60 ± 11.5	0.05
Sex (male/female)	48/11	45/15	0.40
Endoscopic diagnosis			0.37
Atrophic gastritis	31	23	
Gastric ulcer	15	16	
Duodenal ulcer	10	17	

examination. The rapid urease test was inspected for color change up to 2 h at room temperature after addition of the gastric samples. If the color changed from yellow to red, the test was diagnosed as positive. Culture was performed using Columbia agar plates supplemented with 5% horse blood at 37°C under microaerobic conditions. Biopsy samples were fixed in formalin and slides were prepared with hematoxylin and eosin and/or Giemsa staining for *H. pylori* diagnosis. Serum anti-*H. pylori* antibody was measured using a commercial EIA kit (E-plate Eiken *H. pylori* antibody; Eiken Chemical Co., Ltd., Tokyo, Japan). Seropositivity for *H. pylori* antibody was defined by optical density values according to the manufacturer's protocol. Positive result on at least one test was considered to be evidence of *H. pylori* infection.

Patients were assigned randomly by the envelope method to receive either quadruple LACM7 therapy or triple LAC7 therapy. Patients in the LACM7 group received 30 mg lansoprazole twice daily, 750 mg amoxicillin twice daily, 200 mg clarithromycin twice daily and 250 mg metronidazole twice daily for a week. Patients in the LAC7 group received lansoprazole 30 mg twice daily, 750 mg amoxicillin twice daily and 200 mg clarithromycin twice daily for a week (Figure 1).

The outcome of the eradication treatment was evaluated by <sup>13</sup>C-urea breath test (<sup>13</sup>C-UBT) three months after treatment. After overnight fasting, a baseline breath sample was collected and 100 mg of <sup>13</sup>C-urea (UBiT; Otsuka Pharmaceuticals, Tokyo, Japan) was administered with 100 mL of water. Twenty minutes after taking the <sup>13</sup>C-urea, a further breath sample was obtained. Breath samples were analyzed by isotope-selective infrared spectrometry using the UBiT IR 300 (Otsuka Pharmaceuticals). A value of delta-over-baseline higher than 2.5‰ was considered positive. Compliance was checked by pill count. Incidence of adverse events was evaluated by means of a questionnaire at the time they received <sup>13</sup>C-UBT. This questionnaire addressed nine symptoms; diarrhea, taste disturbance, loss of appetite, heart burn, nausea, abdominal pain/ distention, belching, rash and general fatigue. Degree of symptoms were scored as 0 (absent), 1 (mild), 2 (moderate) or 3 (severe).

### Statistical analysis

Characteristics (sex, age, endoscopic diagnoses) between the two groups were compared with  $\chi^2$  test. Eradication

Table 2 Characteristics of patients whose *Helicobacter pylori* status was checked only by serological test

Characteristics	Treatment groups		P value
	LACM7 (n = 52)	LAC7 (n = 44)	
Age (mean) (yr)	63 ± 8.9	63 ± 8.6	0.95
Sex (male/female)	41/11	33/11	0.66
Endoscopic diagnosis			0.34
Atrophic gastritis	24	13	
Gastric ulcer	15	14	
Duodenal ulcer	10	12	

rates between the two arms were compared by intention-to-treat (ITT) and per-protocol analyses. ITT analysis included all patients who were enrolled and randomized to the LACM7 or LAC7 group. For per protocol analysis, patients who were lost to follow-up evaluation or deviated from the protocol were excluded. Eradication rates of these analyses were compared with Fisher's exact test.

Frequencies and degrees of adverse events were evaluated by using  $\chi^2$  test, Fisher's exact test and Wilcoxon rank sum test.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Eradication rate

One hundred and nineteen patients were enrolled in this study: 59 in the LACM7 group and 60 in the LAC7 group. There were no significant differences between age, sex and endoscopic diagnosis (Table 1). However, as serological tests do not always demonstrate a current

Table 3 *Helicobacter pylori* eradication rates

	Eradication	Treatment groups				<i>P</i> value
		LACM7		LAC7		
		<i>n</i>	%	<i>n</i>	%	
ITT analysis	Success	56	94.9	41	68.3	0.0002
	Failure	3	5.1	19	31.7

	Failure	1	1.7	15	26.8	

infection of *H. pylori*<sup>[5]</sup>, we also analyzed eradication rates in a subgroup excluding patients whose *H. pylori* status was checked only by a serological test. There were also no significant differences between the groups in terms of characteristics (Table 2).

After treatment therapy, two patients in the LACM7 group and two patients in the LAC7 group did not appear to have a urea breath test for unknown reasons. One patient in the LAC7 group interrupted eradication therapy because of severe diarrhea. By ITT analysis, *H. pylori* was successfully eradicated from 56 (94.9%) patients in the LACM7 group and 41 (68.3%) patients in the LAC7 group. By per protocol analysis, the eradication rate was 98.3% in the LACM7 group and 73.2% in the LAC7 group (Table 3). The eradication rate for quadruple LACM7 therapy was significantly higher than that for triple LAC7 therapy by ITT ( $P = 0.0002$ ) and per protocol ( $P = 0.0001$ ) analyses (Table 3). The subgroup analyses which excluded patients whose *H. pylori* status was checked only by serological test also showed a significantly higher eradication rate in the LACM7 group (94.2%) than in the LAC7 group (68.2%) ( $P = 0.0009$ , Table 4).

Rash	0 (0.0)	1 (1.9)	0.49
General fatigue	2 (3.6)	1 (1.9)	1.00

### Adverse effects

A total of 110 of 119 patients completed the questionnaire. The incidence of side effects in patients receiving LACM7 quadruple therapy was 42.9%, whereas the incidence in patients receiving LAC7 therapy was 38.9%. No statistically significant difference exists between two groups (RR: 1.10, 95% CI: 0.70-1.73,  $P = 0.67$ , Table 5). The most frequent adverse event was diarrhea in both groups. It was reported in 30.1% in the LACM7 group compared with 24.1% in the LAC group ( $P = 0.53$ ). Other adverse effects such as taste disturbance, loss of appetite, heart burn, nausea, abdominal pain or distention, belching and general fatigue occurred more frequently in the LACM7 group than in the LAC7 group but none was statistically significant. One patient in the LAC7 group complained of a skin rash but it was too mild to quit the eradication therapy (Table 6).

## DISCUSSION

This study was designed as a randomized prospective study to find the effectiveness of LACM7 quadruple eradication therapy and clearly showed that first-line 7-d quadruple therapy using lansoprazole, amoxicillin, clarithromycin and metronidazole significantly improved the

eradication rate of *H. pylori* compared to standard 7-d triple therapy. Furthermore, LACM7 quadruple therapy showed no significant increases in the risk of adverse events.

In the Asia-Pacific consensus guidelines for *H. pylori* infection, the currently recommended first-line eradication therapy is PPI-based triple therapy with clarithromycin and either amoxicillin or metronidazole for 7 d<sup>[11]</sup>. PPI-based triple therapy is also recommended in the Maastricht III consensus report, whereas bismuth-containing quadruple therapy is presented as option<sup>[5]</sup>.

Recently, some non-bismuth quadruple therapies were reported to obtain higher eradication rates<sup>[12]</sup>. Neville reported that the eradication rate of quadruple therapy (lansoprazole 30 mg, amoxicillin 1 g, clarithromycin 250 mg and metronidazole 400 mg, twice daily for 5 d) was 88%<sup>[13]</sup>. Garcia reported that seven day quadruple therapy of PPI, amoxicillin, trinitadazole and bismuth showed a high eradication rate of 84%<sup>[14]</sup>. In randomized control studies, Kateralis compared quadruple therapy (PPI, bismuth, tetracycline and metronidazole for 7 d) with triple therapy (PPI, amoxicillin, clarithromycin) and eradication rates were 82% and 78%, respectively<sup>[15]</sup>. There were some reports of higher eradication rates in quadruple therapies than in triple therapies<sup>[16-18]</sup>. On the other hand, some reports showed better eradication rates in triple therapies than in quadruple therapies. Mantzaris showed that the eradication rate of quadruple therapy (64.8%) was significantly lower than that of triple therapy (78.2%)<sup>[19]</sup>. Some other studies also showed higher eradication rate in triple therapies than in quadruple therapies<sup>[20,21]</sup>. Thus, the effectiveness of first-line quadruple therapy is controversial. In this study, we have demonstrated that the eradication rates were 94.9%/98.3% by ITT/per protocol analyses using LACM7 therapy, which showed a higher eradication rate compared to previous treatment regimens. It seems that LACM7 therapy is superior to other first-line eradication therapies.

However, quadruple therapies have not been prevalent in Japan. The concern is that quadruple therapies may induce more severe adverse events than standard triple therapies. In this study, the overall incidence rate of adverse effects in patients receiving LACM7 therapy was 42.9%, which is higher than that in patients receiving LAC7 therapy (38.9%, Table 5). Diarrhea was the most frequent adverse event which was reported in 30.1% of LACM7 compared with 24.1% of LAC7. Other adverse events that occurred with a frequency of more than 10% were taste disturbance (12.5%) and abdominal pain/distention (12.5%) in the LACM7 group. Nevertheless, the rate of adverse events did not differ significantly between two groups ( $P = 0.06-1.00$ , Table 6). Whereas some previous reports reported that metronidazole induces acute pancreatitis or brain tumors, these effects are extremely rare and are related to high doses or long-term administration<sup>[22,23]</sup>. Metronidazole use in the short-term may be favorable to achieve eradication therapy efficiently.

The serology test, which is non-invasive, is widely

available to diagnose *H. pylori* infection<sup>[5]</sup>. However, as the serology test does not always indicate current infection of *H. pylori*, patients whose *H. pylori* status was checked only by serological test were excluded in subgroup analysis (Tables 2 and 4). In this subgroup analysis, eradication rates of LACM7/LAC7 were 94.2%/68.2%, which were similar to results in Table 3. These results confirmed the efficacy of LACM7 therapy.

Recently, the eradication rates in Japan have been decreasing. In other Asian countries, eradication rates have also been decreasing because of drug resistance. The clarithromycin resistance rate is increasing in many countries. In Japan, clarithromycin resistance currently accounts for approximately 25% compared to around 15% in the 1990s<sup>[7]</sup>. Hence, it is reasonable to use metronidazole for first-line therapy. In addition, clarithromycin is metabolized by the CYP3A4 family of P-450, which is abundant in the liver, and metronidazole is also metabolized in the liver by oxidation. Several drug interactions may occur due to inhibition of oxidative drug metabolism. It was also reported that the combination of metronidazole and clarithromycin induced long-term and concentration-dependent effects<sup>[24]</sup>. On account of these pharmacological effects, combination use of clarithromycin and metronidazole is more effective than using either drug alone.

There is concern that using LACM7 could cause metronidazole resistance. Actually, metronidazole resistance has also increasing and the resistance rate in other Asian countries is 50%-70%, which is higher than in Japan (4.5%)<sup>[25]</sup>. In these countries, metronidazole is frequently used for gynecological infections such as *Trichomonas vaginalis*, which has a high resistance rate. In contrast, metronidazole resistance rate in Japan is lower than in other Asian countries because of the restriction on its use. For these reasons, the influence of short-term use of metronidazole on its resistance might be slight.

Previously, we evaluated 7 d first-line triple therapy with metronidazole (lansoprazole 30 mg, amoxicillin 750 mg, metronidazole 200 mg twice daily for 7 d: LAM) in expectation of a higher eradication rate than other eradication therapies. Eradication of *H. pylori* was achieved in 91.0%, 91.2% and 86.5% of atrophic gastritis, gastric ulcer and duodenal ulcer patients by ITT analyses (data not shown), which were lower than LACM7 (94.9%). These results suggest that metronidazole-containing quadruple therapy is superior to metronidazole-containing triple therapy as first-line eradication.

LACM7 therapy may be useful when confident *H. pylori* eradication is needed; for example, gastric mucosa-associated lymphoid tissue (MALT) lymphoma and idiopathic thrombocytopenic purpura (ITP) that is linked closely to *H. pylori* infection<sup>[26,27]</sup>. As for MALT lymphoma, immediate *H. pylori* eradication is recognized as an effective primary treatment<sup>[5]</sup>. Rapid induction of eradication therapy may reduce tumor size and is expected to prevent undergoing surgical therapy or tumor metastasis if no API2-MALT1 gene translocations exist. As for ITP, when the platelet count is < 3000-5000/ $\mu$ L, immediate

*H. pylori* eradication is strongly recommended to prevent cerebral hemorrhage. Immediate *H. pylori* eradication improves quality of life and decreases the mortality rate. In these cases, to achieve eradication in the first treatment is so important that the LACM7 regimen should be considered for first-line therapy.

## ACKNOWLEDGEMENTS

We sincerely thank Dr. Yoshihiro Hirata and Dr. Yutaka Yamaji from University of Tokyo for some valuable suggestions to the study. We sincerely thank Mr. Tachibana and Ms. Iigaya for the management of the clinical database.

## COMMENTS

### Background

The most widely recommended *Helicobacter pylori* (*H. pylori*) first-line eradication regimen is PPI-based triple therapy (PPI, clarithromycin plus amoxicillin or metronidazole) for at least 7 d. However, the eradication rate of *H. pylori* first-line treatment is decreasing.

### Research frontiers

Various four-drug combination regimens have been reported. Most of them contain bismuth citrate. The research hotspot is how to modify the *H. pylori* eradication therapy to improve its effectiveness.

### Innovations and breakthroughs

Bismuth is not available currently in Japan. Metronidazole is approved only for second-line eradication therapy. Hence, the authors used non-bismuth quadruple therapy (PPI, amoxicillin, clarithromycin and metronidazole) to improve the eradication rate of first-line therapy. The eradication rate in non-bismuth quadruple therapy was significantly higher than standard triple therapy. Nevertheless, the incidence of serious adverse events did not differ between two groups.

### Applications

Non-bismuth quadruple therapy would be helpful to increase the first-line eradication rate in Japan.

### Terminology

Quadruple therapy: therapy with bismuth, two antibiotics and PPI or H2RA.

Non-bismuth quadruple therapy: therapy with PPI, clarithromycin, amoxicillin and nitroimidazole.

### Peer review

In this study, the authors prospectively compared the effectiveness of 7-d quadruple therapy to standard 7-d triple therapy in Japanese patients infected with *H. pylori*. Although many studies have been performed regarding the treatment of *H. pylori* infection, this current study still has its significance, in particular for patients in Japan or in Asia.
