Successful bailout stenting strategy against rare spontaneous retrograde dissection of partially absorbed magnesium-based resorbable scaffold: A case report

Stenting strategy against spontaneous retrograde dissection

Abstract

BACKGROUND

In the development of coronary stent technology, bioresorbable scaffolds are promising milestones in improving the clinical treatment of coronary artery disease. The “leave nothing behind” motto is the premise of the fourth revolution in percutaneous coronary intervention (PCI). Studies proving the safety and efficacy of the magnesium-based resorbable scaffolds (MgBRs) include the BIOSOLVE-I and BIOSOLVE-II trials and the latest BIOSOLVE-IV registry. However, spontaneous retrograde dissection of a partially

A **dissection strategy** with a knuckled guidewire was used around previously placed stents followed by **successful** re-entry into the distal right coronary artery using the Stingray system. The venous cannula was changed to the internal jugular vein and the right common femoral artery and vein were surgically repaired.
