Left ventricular assist device hemolysis leading to dysphagia

Alexander Waschek, Nina Iqbal, Jerry Eutep, Eamon Quigley, David Richards

Abstract

A 41-year-old man with a continuous-flow left ventricular assist device (LVAD) presented for evaluation of dysphagia and dark urine. He was found to have a significantly elevated LDH and an elevated plasma free hemoglobin consistent with intravascular hemolysis. After the hemolysis ceased, both the black urine and dysphagia resolved spontaneously. Transient esophageal dysfunction, as a manifestation of gastrointestinal dysmotility, is known to occur in the setting of hemolysis. Paroxysmal nocturnal hemoglobinuria (PNH) is another recognized cause
