Abstract

Diabetes mellitus is a non-communicable metabolic derangement afflicting several millions of individuals globally. It is associated with several micro and macrovascular complications and is also a leading cause of mortality. The unresolved issue is that of definition of the diagnostic threshold for diabetes. ²⁶ The World Health Organization [WHO] and the American Diabetes Association [ADA] have laid down several diagnostic criteria for diagnosing diabetes and prediabetes based on the accumulating body of evidence. This review has attempted to analyse the scientific evidence supporting the justification of these differing criteria. The evidence for diagnosing diabetes is strong, and there is a concordance between the two professional bodies. The controversy arises when describing the normal lower limit of fasting plasma glucose with little evidence favouring the reduction of the fasting plasma glucose by the ADA.
