NAFLD and COVID-19: a Pooled Analysis

<https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7646222>

Nonalcoholic fatty liver disease is associated with a higher risk of symptomatic, severe, and progressive COVID-19. The association is significant even after adjusting for an important confounding factor, obesity. Hence, it can be concluded that the hepatic manifestation of COVID-19 is independently linked to the severity of coronavirus disease.

Association of Non-alcoholic Fatty Liver Disease (NAFLD) and COVID-19: A literature review of current evidence

NAFLD and COVID-19

Abstract

The Coronavirus Disease-19 (COVID-19) pandemic has swept through nations, crippled economies and caused millions of deaths worldwide. Many people diagnosed with Covid-19 infections are often found to develop liver injury, which, in a small portion of patients, progresses to severe liver disease. Liver injury in the form of elevated transaminases, hyperbilirubinemia and alterations in serum albumin has been observed to be higher in patients with severe forms of the disease. Those who already have insult to the liver from chronic diseases such as Non-alcoholic Fatty Liver Disease (NAFLD)
