Observational study

Pulmonary fibrosis and emphysema: Is the emphysema type associated with the pattern of fibrosis?

Anastasia Oikonomou, Paraskevi Mintzopoulou, Argyris Tzouvelekis, Petros Zazos, George Zacharis, Anastasios Koutsopoulos, Demosthenes Bouros, Panos Prassopoulos

Abstract

AIM: To investigate whether the predominant emphysema type is associated with the high resolution computed tomography (HRCT) pattern of fibrosis in combined pulmonary fibrosis and emphysema (CPFE).

METHODS: Fifty-three smokers with upper lobe emphysema and lower lobe pulmonary fibrosis on (HRCT) were retrospectively evaluated. Patients were stratified into 3 groups according to the predominant type of emphysema: centrilobular (CLE), paraseptal (PSE), CLE = PSE. Patients were also stratified into 3 other groups according to the predominant type of fibrosis on HRCT: typical usual interstitial pneumonia (UIP), probable UIP and nonspecific interstitial pneumonia (NSIP). HRCTs were scored at 5 predetermined levels for the coarseness of fibrosis (Coarseness), extent of emphysema (emphysema), extent of interstitial lung disease
