Observational Study

Relative volume measured with magnetic resonance imaging is an articular collapse predictor in hematological pediatric patients with femoral head osteonecrosis

Davide Ippolito, Alessandro Masetto, Cammillo Talei Franzesi, Pietro A Bonaffini, Alessandra Casiraghi, Sandro Sironi

Abstract

AIM: To assess the potential value of femoral head (FH) volume measurements to predict joint collapse, as compared to articular surface involvement, in post-treatment osteonecrosis (ON) in pediatric patients affected by lymphoproliferative diseases.

METHODS: Considering 114 young patients with lymphoproliferative diseases undergone a lower-limbs MRI examination between November 2006 and August 2012 for a suspected post-treatment ON, we finally considered a total of 13 cases (7 males, mean age 15.2+/-4.8 years), which developed a FH ON lesions (n=23). The MRI protocol included coronal short tau inversion recovery (STIR) and T1-weighted sequences, from the hips to the ankles. During the follow-up (elapsed time: 9.2+/-2 months) 13/23 FHs developed articular deformity. The first MRI studies with
