Cardiac Arrest Due To Massive Aspiration from a Broncho-Esophageal Fistula

Cardiac Arrest Due To Massive Aspiration from a Broncho-Esophageal Fistula

Abstract

BACKGROUND

Tracheo and broncho esophageal fistulas and their potential complications in adults are

seldom encountered in clinical practice but carries a significant morbidity and

mortality.

**CASE SUMMARY** 

We present a case of a 39-year-old otherwise healthy man who presented to our hospital

after ingestion of drain cleaner substance during a suicidal attempt. He unexpectedly

suffered from cardiac arrest during his stay in the intensive care unit. The patient had

developed extensive segmental trachea-broncho-esophageal fistulous tracks that led to

a sudden and significant aspiration event of gastric and duodenal contents with

subsequent cardiopulmonary arrest. Endoscopic evaluation of extension of fistulous

track proved a slow and delayed progression of disease despite initial management

with esophageal stenting for his caustic injury.

CONCLUSION

The aim of this case presentation is to share with the reader the dire natural history of

trachea-broncho-esophageal fistulas and its delayed progression. We aim to illustrate

pitfalls in the endoscopic examination and provide further awareness on critical care

monitoring and management strategies to reduce its morbidity and mortality.

Core Tip: TEF and BEF in the setting of caustic ingestion is an unusual complication associated with high morbidity and mortality. Close monitoring of the gastrointestinal tract patency and motility is critical to avoid gastric distention and large aspiration events with detrimental consequences. Although there is no general consensus on the initial approach to patients with fistula formation, our case proposes serial EGDs and flexible bronchoscopy for at least 6 mo as well as a low threshold for surgical referral when progression of disease or new findings are encountered.

#### INTRODUCTION

Injuries from caustic substance ingestion are associated with varying grades of damage to the gastrointestinal and respiratory tract including esophagitis, mucosal burns, necrosis and perforation, stenosis, and rarely, trachea-esophageal (TEF), and bronchoesophageal (BEF) fistulas. Suicidal caustic ingestion strongly correlates with severity of injury and carries high morbidity and mortality [1]. We present the case of a young man after suicidal caustic ingestion of drain cleaner fluid who developed a sudden massive gastric and duodenal content aspiration into his airway through acquired large TEF and BEF fistulas leading to cardiopulmonary arrest.

#### **CASE PRESENTATION**

#### Chief complaints

A 39-year-old man arrived at our emergency department from another institution where he had been endotracheally intubated for airway protection.

#### History of present illness

The patient had sought medical attention five hours after a suicidal attempt where he ingested an unknown amount of drain cleaner liquid that contained sodium hydroxide, potassium hydroxide, and carbonyl diamide.

#### 2 History of past illness

The patient had a free previous medical history.

#### Personal and family history

None reported

#### Physical examination

Upon arrival to our facility, his vital signs were stable. His physical exam revealed edematous oral mucosa and chemical injuries to the face.

#### Laboratory examinations

His initial laboratory data was remarkable for a white blood cell count of 12.9x 10<sup>3</sup>/uL and a D-dimer >5250 ng/mL DDU.

#### Imaging examinations

Chest computer tomography (CT) with contrast revealed thickening and submucosal edema of the esophageal and gastric wall, along with trace para-esophageal and perigastric stranding and fluid. No free air was reported.

#### **FINAL DIAGNOSIS**

Tracheo and broncho esophageal fistulas leading to massive aspiration and cardiac arrest.

#### **TREATMENT**

He was started on a proton pump inhibitor, intravenous fluids, and prophylactic antibiotics. A tracheostomy and jejunostomy tube were placed on hospital day 13. He was noted to have bouts of coughing during routine sedation-awakening trials and with reduction in sedatives. On hospital day 18, he became acutely hypoxic, and his oxygen saturation decreased to 50% followed by pulseless electrical arrest. Advanced cardiopulmonary resuscitation was initiated with recovery of spontaneous circulation after two 5-minute rounds of cardiopulmonary resuscitation. Copious amounts of frothy, yellow-tinted secretions were noted from the tracheostomy in-line suction setup. No oral secretions were noted during oral cavity suction. A nasogastric tube was placed for gastric cavity decompression and approximately 400-500 mL of fluid were suctioned. Figure 3 demonstrates chest imaging obtained prior and post cardiopulmonary arrest highlighting the patient's acute clinical change. On day 22, the patient underwent successful placement of a 1.8cm in outer diameter and 12.3cm in length fully covered esophageal stent.

The patient's hospital course was complicated by acute respiratory distress syndrome and recurrent septic shock secondary to aspiration pneumonia. He was eventually liberated from mechanical ventilation and transitioned to a tracheostomy collar. He continued on enteral nutrition through a jejunostomy feeding tube. He left the intensive care unit on day 40 and was discharged home with home-health on day 114.

### **OUTCOME AND FOLLOW-UP**

His endoscopy surveillance revealed progression and further extend of disease. Bronchoscopy performed after 17 wk revealed new tracheoesophageal fistula with esophageal lumen opening at midway through posterior wall of the trachea (Figure 4A, 4B). His prior bronchoscopy at 7 wk had shown protrusion of esophageal stent through the left main broncho-esophageal fistula without any additional fistulous tracts (Figure 4C). Esophagoduodenoscopy performed 7 mo after initial presentation visualized tracheostomy tube through a combined lumen formed by the esophagus and trachea (Figure 4D). Distal to the tracheostomy tube, a double lumen is identified with the

esophagus opening at the proximal end of the stent (Figure 4E) as well as a complete obliteration of the stent in his distal end due to in-growth tissues (Figure 4F). The patient has been referred for cardiothoracic surgical evaluation where he will complete nutritional optimization prior to potential surgical intervention. Chronology of events is listed in Table 1.

#### **DISCUSSION**

Caustic ingestion remains a rare but potentially catastrophic mechanism for injury leading to significant morbidity and mortality. Specific management guidelines have yet to be defined [3]. Injury severity is determined by multiple factors including type of agent, its concentration, amount consumed, and time of contact with gastrointestinal mucosa. Agents can be either acidic or alkali. Our patient ingested drain cleaner liquid, predominantly an alkali substance.

TEF is a delayed and unusual complication that occurs approximately in 3% of patients with caustic ingestion <sup>[3]</sup>. BEF are not extensively described in the literature and their true incidence unknown. The rarity of BEFs is likely due to the anatomical relationship between the left mainstem bronchus and the esophagus. The thoracic esophagus extends caudally towards the diaphragmatic hiatus, passing posteriorly to the trachea, the tracheal bifurcation, and the left main stem bronchus <sup>[4]</sup>. The area of contact of the posterior wall of the left main bronchus with the anterior wall of the esophagus, in contrast to that of the trachea, is significantly smaller, making left main BEFs less likely to develop than TEF.

Hemorrhage, thrombosis, and inflammation with edema occur within the first 24 h. If caustic ingestion is severe enough, transmural necrosis leads to perforation and regional fistulous tract formation. TEFs and BEFs can lead to sepsis, aspiration pneumonia, ARDS, strictures, malignancy among other systemic complications [3]. In our patient, the fistulous tract was significant enough to allow for large amounts of gastric and duodenal content to reach the airway causing hypoxemia and cardiopulmonary arrest.

Medical literature on the incidence of cardiopulmonary arrest due to aspiration through a BEF is lacking, and its incidence is not defined. We infer that our patient's aspiration leading to his arrest was due to increased output through a persistently large fistulous track in the setting of transient duodenal outlet stenosis from mucosal damage and impaired gastrointestinal motility. Our patient exhibited large amounts of bile-colored tracheal secretions in the peri-arrest period confirming a high output fistulous passage of duodenal content. Although in our case the volume we aspirated through nasogastric suctioning was 400-500 mL, the exact volume of gastric content aspirated is unknown. However, it was large enough to infiltrate the lingula and left lower lobe.

The incidence of aspiration pneumonia related to corrosive ingestion has been estimated in up to 4.2% of cases with a mortality up to 60% <sup>[5]</sup>. Due to high risk of aspiration, enteral nutrition is often restricted <sup>[5]</sup>. In addition, caloric restriction and malnutrition further lead to recurrent pulmonary infections, bronchopneumonia, and sepsis <sup>[6]</sup>. Alternative means of enteral nutrition through the insertion of a jejunostomy tube were sought in our patient to enhance nutritional state as well as to promote fistula healing. A high index of suspicion should be maintained for functional or anatomic gastrointestinal tract obstruction as a consequence of caustic injury and should be considered when addressing nutritional support to select the most suitable nutritional route.

Risk stratification is needed during the initial approach. Symptoms such as dysphagia, hematemesis, stridor, cough, respiratory distress, drooling, and abdominal pain have been described. A sudden bout of uncontrolled paroxysmal cough, a reported symptom associated with BEF <sup>[7]</sup>, was witnessed in our patient while mechanically ventilated during daily sedation awakening trials suggesting aspiration events and persistent fistula.

There is no consensus within the medical community of the initial and emergent management of TEF/BEF after caustic ingestion. In 2015, the World Society of Emergency Surgery recommended a management algorithm which includes both endoscopy and CT imaging as part of the initial assessment (Figure 5) [8]. Our patient

underwent both, EGD and non-contrast CT scan within the first twenty-four hours of ingestion. In order to quantify the severity of the injury, we utilized the Zargar classification system which placed him in the IIIB category [9]. This grading is useful for predicting systemic complications, respiratory failure, nutritional autonomy, and survival. In general, the degree of esophageal injury at endoscopy is a predictor of systemic complication and death with a 9-fold increase in morbidity and mortality for every increased injury grade [2] which aligns with our case study. An important tool for the clinician about risk rather than timing.

However, risk stratification cannot accurately predict the depth of necrosis which could lead to inappropriate non-operative management and/or unnecessary surgical resection [3]. In order to properly evaluate the extent of necrosis, we propose that there is a benefit for surveillance endoscopic examination through EGD and flexible bronchoscopies for early fistula detection and therapeutic interventions. This would also serve for the monitoring of long term sequelae such as airway stenosis, or such in our case, further development of fistulous tracks. The interval of bronchoscopies would be dictated by endoscopic findings. In our case, evidence of a large newly detected TEF occurred 4 mo after the initial event. Prior biweekly and monthly bronchoscopies only reported the known BEF. It is reasonable to suggest monthly endoscopic surveillance in patients with high Zargar Score for at least 4-6 mo following the initial ingestion. In patients who are able to be discharged from the hospital, surgical referral should be sought if endoscopic examination does not show a favorable course, new fistulous tracks are detected, or if the patient's symptoms severely impair quality of life.

The treatment of TEFs and BEFs is based on previous case reports, reviews, and case series, along with experts' opinions. In our case, a multidisciplinary team agreed on the placement of an 18mm x 123mm fully covered esophageal wall stent. According to the World Journal of Emergency Surgery, endoscopic treatment is the gold standard for closing large esophageal defects such suspected in our patient for the exam of injury during initial endoscopic examination. Self-expandable stents have showed to have a higher success rate and lower mortality rate when compared to surgical approach [10].

Our patient underwent self-expandable sent placement due to the clinical complexity and added surgical risk in the setting of a recent cardiac arrest. This case illustrates both the prolonged hospital course of a cardiac arrest survival due to delayed complications of a BEF associated with functional impairment and also the protracted progression of the disease more than 6 mo later.

#### **CONCLUSION**

In conclusion, TEF and BEF in the setting of caustic ingestion is an unusual complication associated with high morbidity and mortality. Early and frequent endoscopic evaluation of the upper gastrointestinal tract and bronchial tree, as well as maintaining a high index of clinical suspicion, are necessary for its prompt recognition. This will lead to early detection of delayed complications including new fistulous tracks, and timely institution of therapeutic interventions. We remind the reader of the importance of close monitoring of the gastrointestinal tract patency and motility to avoid gastric distention and large aspiration events with detrimental consequences. Although there is no general consensus on the initial approach to patients with fistula formation, our case proposes serial EGDs and flexible bronchoscopy for at least 6 mo as well as a low threshold for surgical referral when progression of disease or new findings are encountered.

#### ACKNOWLEDGEMENTS

The authors would like to acknowledgment Dr. Hector Gonzalez and Dr. Arian Bethencourt-Mirabal for the revision provided to the manuscript, and Dr. Steven Kaplan, Dr. Daniel Heller and Dr. Dionne Morgan, for their insight on the esophagoduodenoscopic and bronchoscopic findings.
