Facial emotion perception in schizophrenia: Does sex matter?

Jasmine Mote, Ann M Kring

Abstract

Facial emotion perception (FEP), or the ability to identify the emotion on another person's face, is an important aspect of social functioning. People with schizophrenia show deficits in FEP when compared to people without schizophrenia, and these deficits are associated with poorer functioning and more severe symptoms. Less is known about how women with schizophrenia compare to men in FEP; however, men with schizophrenia have more severe deficits in social functioning compared to women with schizophrenia. Through further assessing sex differences in FEP, researchers and clinicians can better understand other sex differences observed in the disorder as well as further develop treatment targets to help improve functioning in people with schizophrenia. This review will summarize and critically evaluate the literature on FEP in chronically ill adults with schizophrenia, people with early (onset prior to age 18) or recent-onset (experiencing their first or second psychotic episode or illness duration less than 2 years) schizophrenia, and unaffected first-degree relatives of people with schizophrenia, focusing on the available evidence related to sex differences in FEP across the schizophrenia spectrum. We will discuss the limitations of existing research as well as considerations and implications for future studies examining sex differences
