**SPECIFIC COMMENTS TO AUTHORS**

In this review, Marina Tusup , Thomas Kundig and Steve Pascolo have systematically analyzed the most relevant post-transcriptional RNA modifications reported in the literature and have elucidated their potential role in regulating cancer initiation and progression. This is a good manuscript, dealing with very interesting topics in a

rapidly emerging area. My only concern is related to the lack of a summarizing section that helps the reader to understand the general meaning of the data presented. I suggest to improve the manuscript with the addition of some sentences (in particular in section 1) including a more critical analysis of the biological and clinical relevance of the findings reported. Minor points: pag 8. The second sentence at the beginning of section 2.1 ("It is suggested that tumorigenesis ....") is not clear: it should be rewritten in order to become more easily comprehensible by the reader. pag 8. In the second paragraph of section 2.1 ("Translation of these proteins relies ....") the mechanism of IRES mRNA translation initiation should be explained in more details: note that every cellular mRNAs have a 5' cap but IRES dependent translation is active only in specific conditions. pag 10. The two first paragraphs should include more references. See for instance the references reported in a recent review by Penzo et al. (Pseudouridylation in physiology and medicine: for better and for worse. *Genes* 2017; 8(11), 301). Figures are too simple and schematic: they should be enriched by a more detailed description and improved in the graphics quality. In conclusion, I recommend the paper for publication in the *World Journal of Clinical Oncology*, but it should be revised taking into account these comments and remarks before being accepted.
