Title: Prognostic values of hemodynamic indices in patients with sepsis after fluid resuscitation

Reviewer's code: 02447396

SPECIFIC COMMENTS TO AUTHORS

The most commonly used therapy for the treatment of sepsis is fluid resuscitation which aims to maintain hemodynamic stability and slow progression of the disease. The most frequently monitored hemodynamic indices probably include heart rate, cardiac index, mean arterial pressure, systemic vascular resistance index, central venous pressure and central venous oxygen saturation. In this brief study, the authors discussed the prognostic values of hemodynamic indices in patients with sepsis after fluid resuscitation to provide data to promote the treatment for sepsis. This study is very interesting. Total 120 patients were included and the methods are very clear. The results are well present, and achieved the objectives in this study. Minor comments: 1. The manuscript should be edited. A minor language polishing should be revised. 2. The tables should be edited. The table 3 should be deleted, and the data can be added into the main text. 3. The references are updated, and well discussed.

Answer: Thank you very much for your comments. The authors revised the manuscript according to the reviewer's comments. The details are listed below:

1. The manuscript should be edited. A minor language polishing should be revised.

Answer: The manuscript was edited carefully, and the language was proofed and revised again.

2. The tables should be edited. The table 3 should be deleted, and the data can be added into the main text.

Answer: Tables were edited. Tables was deleted, and the data were moved to the main

text.

3. The references are updated, and well discussed.

Answer: Thank you very much.
