### **Reviewer's comments**

A Major operation of bone tumor refers to the operation of bone tumor of spine, pelvis and limbs; in such cases, in order to obtain an ideal resection boundary, it is necessary to expose and potentially damage a wide range of anatomical areas. Reducing or avoiding factors that can negatively impact the management of patients who underwent bone tumor surgery, and promoting their rapid postoperative rehabilitation are important clinical priorities. Enhanced recovery after surgery is a series of perioperative optimization measures based on evidence-based medicine, which can reduce the physiological and psychological trauma stress, reduce complications, shorten the length of hospital stay, and promote the postoperative rehabilitation of patients. This study evaluated the effect of enhanced recovery after bone tumor surgery in the perioperative management in China. The authors found that the application of the enhanced recovery after surgery protocol in the perioperative period of patients with bone tumor surgery can shorten the hospital stay, reduce the incidence of postoperative nausea and vomiting, reduce postoperative pain. The study is very interesting, the results are well display and discussed. After a minor revision, it can be accepted. Comments: 1. The manuscript requires a minor editing. Some minor spelling mistakes should be corrected. Such as, "Ttem" in table 1, should be "Item". 2. The references should be edited and updated.

**Reply:** *Thanks for your constructive suggestion, and we have revised the manuscript according to your comments.*

- 1. We have checked the spelling mistakes throughout, and have corrected the word "Item" in Table 1.*
- 2. We have updated the references, and edited them according to the guideline.*
