Abstract

Pancreatic cancer produces disabling abdominal pain, and the pain medical management for pancreatic cancer is often challenging because it mainly relies on the use of narcotics (major opioids). However, opioids often provide suboptimal pain relief, and the use of opioids can lead to patient tolerance and several side effects that considerably reduce the quality of life of pancreatic cancer patients.

Endosonography-guided celiac plexus neurolysis (EUS-CPN) is an alternative for pain control in patients with nonsurgical pancreatic cancer; EUS-CPN consists of the injection of alcohol and a local anesthetic into the area of the celiac plexus to achieve chemical ablation of the nerve tissue. EUS-CPN *via* the transgastric approach is a safer and more accessible technique than the percutaneous approach.

We have reviewed most of the studies that evaluate the efficacy of EUS-CPN and that have compared the different approaches that have been performed by endosonographers. The efficacy of EUS-CPN varies from 50% to 94% in the different studies, and EUS-CPN has a pain relief duration of 4–8 weeks. Several factors are involved in its efficacy, such as the onset of pain, previous use of chemotherapy, presence of metastatic disease, EUS-CPN technique, type of needle or neurolytic agent used, *etc.* According to this review, injection into the ganglia may be the best technique, and a good visualization of the ganglia is the best predictor for a good EUS-CPN response, although more studies are needed. However, any of the 4 different techniques could be used to perform EUS-CPN effectively with no differences in terms of complications between the techniques, but more studies are needed. The effect of EUS-CPN on pain improvement, patient survival and patient quality of life should be evaluated in well-designed RCTs. Further research also needs to be performed to clarify the best time frame in performing an EUS-CPN.

Core Tip: In this review, we analyzed the efficacy of the celiac plexus neurolysis through echoendoscopy (EUS-CPN) technique in patients with unresectable pancreatic cancer.

The use of opioids for pain control are associated with numerous side effects that reduce the quality of life of pancreatic cancer patients, and the use of EUS-CPN is a safe and effective approach to pain management and allows for the reduction in the opioid doses used. There are different techniques to perform an EUS-CPN, all of which are described in this article. However, there are concerns about the efficacy of EUS-CPN (since it produces a reduction in pain for a short time), the ideal time to perform this technique is unknown, and it is also unknown whether this technique has any influence on patient survival and quality of life.

INTRODUCTION

Pancreatic cancer is one of the solid tumors with the worst prognosis. Unfortunately, it is often diagnosed at an advanced stage of the disease, and only 12–20% of cases are resectable at the time of diagnosis. Over 50% of patients with pancreatic cancer will not survive within the first year after diagnosis, and this disease has an overall five-year survival rate under 10%^[1,2].

Chronic abdominal pain is a frequent symptom in patients with advanced pancreatic cancer due to the perineural invasion of tumor cells, and pain is present in 70–90% of the patients at diagnosis and has very complex medical management^[3,4].

Pain management in patients with pancreatic cancer usually begins with the administration of nonopioid analgesics followed by opioids in refractory cases. Opioids have many adverse effects, such as nausea, constipation, urinary retention, drowsiness, and patient tolerance or dependence.

Currently, many other therapeutic alternatives have been evaluated as complementary treatments, such as celiac plexus neurolysis (CPN) with various agents, which can be administered either percutaneously or transgastrically^[5,6].

Pain originating in the intra-abdominal viscera, such as the pancreas, is transmitted by the afferent nerve fibers through the celiac plexus and finally reaching the central nervous system through the posterior root of the spinal cord at the level of T12-L2. The celiac plexus is a group of nerve fibers that converge into the celiac ganglia located in the retroperitoneum and is immediately adjacent to the anterolateral wall of the aorta at the origin of the celiac trunk. Traditionally, access to the celiac plexus has been percutaneous, and it is necessary to avoid the different structures located between the skin and the celiac plexus while performing a percutaneous access to the celiac plexus^[5]. However, endosonography (EUS) allows the endosonographer to perform CPN close enough to the celiac plexus through the gastric wall, which could allow a safer and more effective access. EUS-CPN was first described by Wiersema *et al* in 1996^[6].

EUS-CPN is performed by the injection of a neurolytic agent directly into the celiac plexus, which causes an irreversible ablation. Pure ethanol is often used as the neurolytic agent in association with a local anesthetic agent, such as bupivacaine, and nociceptive afferent

nerve fibers are blocked with these agents to achieve pain reduction. EUS-CPN is performed to ameliorate pain and reduce the dose of analgesics in these patients, because the use of analgesics often causes a reduction in patient survival or quality of life.

In this review, we focused on patients with unresectable pancreatic cancer because pancreatic cancer is common and still affects a large number of cases. The options for pain management in these patients must be understood by all gastroenterologists and endoscopists. However, other pathologies, such as biliary tract tumors and patients with chronic pancreatitis, may require a CPN or celiac plexus block, respectively. Due to the large amount of evidence for the use of EUS-CPN in unresectable pancreatic cancer patients, we wanted to focus on this pathology to avoid performing such an extensive review and to focus on the management of chronic abdominal pain with this technique. We also wanted to further understand whether our interventions in this specific pathology have any impact on the survival and quality of life of patients.

INDICATIONS

EUS-CPN is performed in patients with chronic or uncontrolled abdominal pain associated with nonresectable pancreatic cancer; however, to ensure that EUS-CPN is effective, we must carefully select the patients who receive this technique. Current evidence does not precisely indicate when the best time is to perform an EUS-CPN^[7].

EUS-CPN is useful in patients with uncontrolled pain or when the adverse effects of opioids reduce the patient's quality of life. Furthermore, other causes of pain must be investigated and ruled out prior to treatment, such as carcinomatosis, liver or bone metastases and peptic ulcers, because these conditions could lead to a partial or non-response to EUS-CPN.

CONTRAINDICATIONS

EUS-CPN should not be performed in patients with resectable pancreatic tumors because this technique may be difficult to perform, and it is mandatory to discuss borderline patients within a multidisciplinary team before performing an EUS-CPN. There are no

absolute contraindications, but there are certain situations where an EUS-CPN should not be performed. The contraindications of EUS-CPN are shown in **Table 1**.

TECHNIQUE

Over the years, CPN has been performed via different techniques. It was initially described in 1914 as an intraoperative procedure^[8], and since then, assistance with fluoroscopy, computed tomography or abdominal ultrasonography has been utilized^[5]. In 1996, Wiersema described for the first time an endosonography-guided celiac plexus neurolysis (EUS-CPN) by a transgastric approach^[6]. EUS-CPN allows for a more accurate and safer technique due to the use of color Doppler to avoid vessels that could be close to the needle path. It can be performed in an outpatient setting depending on the clinical status of the patient.

STEPS

Patient medical records must be reviewed to rule out previous surgeries or anatomical abnormalities and to evaluate the radiological images to study the location of the lesion, to evaluate for any possible infiltration of the celiac trunk and to determine if there is another pathology present.

The left decubitus position is the preferred position to perform an EUS-CPN. Deep sedation is also recommended for patients undergoing an EUS-CPN along with appropriately monitored anesthesia. The breathing rate, pulse oximetry, blood pressure and heart rate of the patients must be thoroughly monitored throughout the procedure.

The administration of at least 500 mL intravenous saline solution is needed before and after the procedure to minimize the risk of hypotension, as hypotension is one of the most common adverse effects after the procedure, only second to the hyperactivity of the parasympathetic nervous system^[3,11,12,14,17,20,22,26].

The evidence is not clear regarding the administration of prophylactic antibiotics for EUS-CPN. Infectious complications due to EUS-CPN are rare, so most of the previous studies did not use prophylactic antibiotics^[14,17,20,22].

An examination with radial echoendoscopy may be initially performed to explore the celiac trunk area. Then, a linear echoendoscope is introduced until reaching the origin of the celiac trunk, which is the first large vessel of the abdominal aorta just beneath the diaphragm. The diaphragm is a structure indirectly located by the visualization of the left diaphragmatic crus, 40–45 cm distal to the superior dental arch. Immediately under the celiac trunk is the origin of the superior mesenteric artery and the myenteric plexus **(Figure 1)**.

The celiac plexus is located in the anterior wall of the aorta and is on both sides of the origin of the celiac trunk, and it is sometimes 1 mm above it or can sometimes be several millimeters below it **(Figure 2)**. To locate this area, the echoendoscope should be rotated both clockwise and counterclockwise. The puncture area must be carefully selected, and before introducing the needle, it is recommended to use color Doppler in the target area of the puncture to make sure there are no vascular structures in the path of the needle.

TYPE OF NEEDLE

Any EUS needle may be used, as previous demonstrated in several studies, and these needles can range from small caliber needles, such as 25-gauge needles, to larger caliber needles, such as 19-gauge needles. Certainly, the use of a larger caliber needle will allow for an easier injection of substances.

One specific needle was designed for this technique: it is a 20-gauge needle with a dumpling pattern and conical tip (EchoTip® Ultra Celiac Plexus Neurolysis Needle, Cook Medical, Limerick [Ireland]), which allows the injection to be sprayed in a radial and uniform way and allows for adequate diffusion of the substance into the celiac plexus **(Figure 3)**.

When the puncture area is selected, the needle must be primed with local anesthetic (usually bupivacaine or lidocaine) to avoid the injection of air into the puncture area.

Once the needle has been introduced, aspiration to confirm negative pressure must be performed to make sure that the needle was not placed into a vessel prior to injecting the substance, because the injection of these substances in a blood vessel wall or into the systemic circulation can be critical and life threatening.

NEUROLYTIC AGENT

Usually, the average injected volume of 0.25% bupivacaine is 10 to 20 mL, followed by 10 to 20 mL of 98% alcohol, although these quantities may vary slightly depending on the study. Optionally, some contrast agents can be used, even though the use of these is not clear. Ishiwatari *et al* compared the use of phenol as compared to ethanol as a neurolytic agent and found no differences in pain control or complications^[9].

TYPE OF APPROACHES (Figure 4)

Bilateral approach/technique^[6,10]: once the celiac trunk has been located, the objective of this approach is to inject substances on both sides of it. It is recommended to make slow and rotatory clockwise movements without losing the longitudinal axis of the aorta. With these movements, we are able to see the “injection windows”, as shown in **Figure 5**.

Central approach/technique^[11,12]: is begun from the starting position at the origin of the celiac trunk and without losing the longitudinal axis of the aorta, the injection is performed in a cranial plane from the starting position, as shown in **Figure 6**.

Broad approach/technique⁽¹³⁾: was first described in 2010 by Sakamoto *et al*, and this approach is based on the injection of the substances above and on both sides of the origin of the superior mesenteric artery, without losing the longitudinal axis of the aorta, and by aiming for a broader diffusion of the neurolytic agent (**Figure 5**). In this technique, the needle reaches a greater depth; therefore, it is recommended to use a 25-gauge needle.

Direct approach/technique⁽¹⁴⁾ is based on the direct injection of each celiac ganglia to distribute the alcohol and anesthetic doses. Celiac ganglia are sometimes visible as hypoechoic structures, which are almond shaped, are between 2 to 20 mm and are usually located around the aorta at the origin of the celiac trunk. The right celiac ganglion is usually located 6 mm inferior to the origin of the celiac trunk, while the left celiac ganglion is located 9 mm below the origin of the celiac trunk. During the injection in the center of the ganglia, “ballonization” and an increase in volume will be seen. If this is not seen, the needle is probably misplaced.

AFTER THE PROCEDURE

Before extracting the needle, 3 mL of saline solution is injected to prevent the injection of ethanol into the path of the needle. If this injection of saline is not performed, it could result in the exacerbation of pain after the procedure. Patients should be monitored for at least two hours after the intervention, and the patient's blood pressure should be monitored.

RESULTS

The efficacy, study design, dose and type of neurolytic agent, follow-up and complications of EUS celiac plexus neurolysis are summarized in **Table 2**.

EFFICACY OF CELIAC PLEXUS NEUROLYSIS

Several studies have been performed to evaluate the efficacy of EUS-CPN. Globally, there has been a great variability shown in the efficacy of this technique for pain control associated with pancreatic cancer. The range of efficacy varies from 50% to 94% in the previous studies^(6,7,9-23).

However, the available current literature has limitations due to the different quality of the studies (some of them are retrospective), and they differ in the injection technique, type and volume of neurolytic agent, number of patients and follow-up. In addition, the definitions for categorizing pain control vary in the different studies: improvement or resolution of pain, reduction of the Visual Analogue Scale (VAS) or Likert scale, reduction of the dose of opioids, etc^(6,7,9-23).

EUS-CPN was first performed by Wiersema *et al* with an efficacy of 88% in 30 patients over 10 weeks[6]. In the first clinical trial, Wyse *et al* randomized 96 patients with unresectable pancreatic cancer to either early treatment with EUS-CPN or a conventional medical treatment with analgesics and opioids. Clinical significance was observed with a reduction of 28% and 60% in the Likert scale at 4 and 10 weeks of follow-up, respectively. A reduction in the dose of analgesics was also observed^[7].

Momentary efficacy was observed in four systematic reviews and three meta-analyses. The studies demonstrated a reduction in pain in more than 50% of the patients during the 4–8 week follow-up^[24-27]. In addition, one of the systematic reviews concluded that pain control allowed for a reduction in the opioid dose with significantly fewer adverse effects in the treated group ($p < 0.0001$), but this was during the short term.

Based on this evidence, we can conclude that EUS-CPN significantly reduces the pain associated with pancreatic cancer (but does not make the pain disappear completely) and can reduce the dose of opioids^[7,21,24,25]. The combination of an EUS-CPN plus analgesic opioids could be superior to opioid therapy alone^[7]. However, this should be demonstrated in randomized clinical trials (RCTs) to further validate these findings^[25,28].

IMPACT OF CPN ON QUALITY OF LIFE AND SURVIVAL

Current evidence supports the efficacy of CPN. However, the effect on the patient's quality of life is controversial, and there is no effect on survival. Changes in the quality of life were measured with different QOL scores Digestive Disease Questionnaire-15^[7].

On the one hand, Wyse *et al* observed that the addition of EUS-CPN to the treatment regimen had no outcomes effect on the quality of life in patients^[7]. Lu *et al* found in a their systematic review that EUS-CPN significantly reduced significantly the dose of opioids with a diminution of their adverse effects, but there wiwasth no differences in terms of quality of life^[24].

On the other hand, Seicean *et al* found little improvement in some factors associated with quality of life, such as the functional status or sleep quality, and there was no change in the acceptance of the disease and enjoyment of life^[19].

Current evidence has not shown any clinical significance in terms of survival to recommend an EUS-CPN^[7,25]. Although it has not been demonstrated that EUS-CPN significantly improves the quality of life of patients, the reduction of adverse effects associated with opioids could have some impact on the quality of life of these patients, which can be important^[19, 25].

PREDICTORS OF RESPONSE

Celiac plexus neurolysis is usually performed as a palliative treatment in patients refractory to common analgesics. However, since Wiersema *et al* performed the first EUS-CPN, they found that patients who had not received previous chemotherapy had significantly greater pain relief than patients who received chemotherapy^[6].

It is known that chemotherapy improves the patient's pain and quality of life^[7,23]. Patients who received chemotherapy before EUS-CPN could be impacted by the effect of the technique. In fact, as concluded by Wyse *et al*, pain improvement was seen earlier in patients who had not received previous chemotherapy than in patients who did receive chemotherapy^[7].

In a different study, Si-Jie *et al* observed a significant improvement in the pain scales of the patients who had an onset of pain earlier than 3 months, and an improvement of pain was then observed in both the short and long terms^[21].

The best time to perform an EUS-CPN remains unclear^[7]. It could be possible that a delay in performing an EUS-CPN or its application in patients who have received other treatments for pain control could decrease the efficacy of the EUS-CPN; however, there is not enough evidence to support this theory^[7,10,18].

Few studies have also compared the different techniques of EUS-CPN^[11,17,21,22,25,26]. Iwata *et al* observed that the direct invasion of the celiac plexus and the distribution of ethanol on only the left side of the artery negatively influenced pain control^[20].

A retrospective study by Ascunce *et al*^[16] evaluated the efficacy of the bilateral technique. They concluded that the direct visualization of the celiac ganglia while performing an EUS-CPN (which needed to be referenced in the endoscopic report) was a good predictor of the response (OR 15.61).

BILATERAL vs. CENTRAL TECHNIQUE

As mentioned above, there are several techniques for performing an EUS-CPN. We reviewed those studies that compared the different techniques to analyze which technique may be the most effective and that had fewer adverse effects^[11,13,18,20,22,23].

On the one hand, bilateral and central techniques have shown comparative outcomes in a few studies^[12,24,25], and the only exception was in a study performed by Sahai *et al.* in 2009. The bilateral approach improved the pain control compared to the central technique (70.5% vs. 45.9%; $p < 0.05$), but the effect lasted only one week^[11].

On the other hand, in a meta-analysis published in 2009, a subgroup analysis was performed that evaluated the different approaches that were performed. The bilateral approach was more effective than the central technique in terms of pain control (84.5% vs. 45.9%; $p < 0.05$)^[26].

Finally, one more recent meta-analysis of 437 patients concluded that comparable pain control was obtained with both approaches; however, the bilateral approach significantly reduced the dose of opioids compared to the central technique^[24].

GANGLIA INJECTION

Direct injection of neurolytic agents into the ganglia has been demonstrated to be effective for pain relief associated with pancreatic cancer. The rate of effectiveness has varied from 65% to 94% in different studies,^[14,20,22] and one of these studies was a clinical trial. Doi *et al.* demonstrated significant pain relief with the injection directly into the ganglia compared to the central approach, but the injections were only beneficial for one week (73.5% vs. 45.5%)^[20].

Despite having good results in several studies, other studies have been published that have shown some concerns regarding this technique.

Levy *et al.* published a randomized double blind clinical trial comparing direct ganglia injection to central celiac plexus neurolysis, and no differences were found in pain control or in improving the quality of life with either technique. However, the median survival was significantly higher in patients treated with direct ganglia injection (10.5 months vs. 5.6 months), particularly for patients with nonmetastatic disease^[23].

Recently, Kouloris *et al.* performed a systematic review and meta-analysis on the efficacy of three EUS-CPN techniques on pain control: central, bilateral and ganglia injection. Pain control was achieved in 68% of the patients at week 2 and 53% of the patients at 4 weeks of follow-up. There was no difference between the techniques in terms of age, sex, tumor localization, stage or baseline pain before the intervention. Major bias could have been

present in this review, because low-quality studies were included (not randomized studies), the measurement of treatment response was different, and the influence of other treatments (opioids or chemotherapy) was not evaluated in this study. However, no differences in the complications between the techniques were found^[28].

CPN OVER THE MESENTERIC ARTERY (BROAD TECHNIQUE)

Few studies have evaluated the broad technique or have compared it to the other techniques. Sakamoto *et al* compared the broad CPN technique against the bilateral technique, and this study showed that there was better pain control with the broad approach at 7 and 30 days of follow-up. There were no differences in the adverse events^[13]. Another study comparing the broad CPN technique against the broad CPN plus direct ganglia injection technique showed significantly better pain control with the combination of both techniques (OR 3.69 in the 1st week and OR 6.37 in the 1st month)^[22]. Adequate pain management has been obtained by this approach of using both techniques, but more studies are needed to confirm these findings.

COMPLICATIONS

EUS-CPN is described as a safe procedure^[6,7,9-23]. A total of 44% of complications have been reported, but most of them have been minor and transient. Diarrhea and interim hypotension are frequently observed due to the parasympathomimetic response. Pain exacerbation is another common adverse effect (8%) associated with ethanol injection. Transient inebriation was observed in three Japanese studies^[9,20,22].

Major complications have been reported in less than 1% of patients; however, these patients frequently have fatal outcomes. Infection, bleeding, retroperitoneal abscesses, paraplegia and ischemia have been previously reported in the literature^[29-34]. Usually, these complications are associated with an incorrect injection site of the neurolytic agent. EUS-CPN must be performed by expert endoscopists and at hospitals with a high volume of procedures.

NEW TECHNIQUES OF EUS-CPN

Recently, other techniques of EUS-CPN have been described with encouraging results. In 2012, Wang *et al* achieved an EUS-CPN by the insertion of a radioactive seed, I¹²⁵, directly into the celiac ganglia. Twenty-three patients were included in this study, and there was a significant reduction in pain control and the dose of opioids^[35].

In 2015, Facciorusso *et al* suggested in a case report that the use of an EUS-CPN associated with the injection of ethanol directly into the tumor could enhance the effects of neurolysis; however, more studies of this approach are needed to confirm the results^[36]. Recently in 2019, Bang *et al* published that an EUS-CPN could be performed with a radiofrequency ablation of the celiac ganglia. Twelve patients were included in this study, and they compared this technique against the traditional EUS-CPN. Radiofrequency ablation obtained better results not only regarding the pain associated with pancreatic cancer, but there was also an improvement in the quality of life scales^[37]. However, more studies are needed to validate these approaches.

CONCLUSION

EUS-CPN is a safe and effective therapeutic alternative for short-term pain control in unresectable pancreatic cancer patients. It can allow for a dose reduction of opioids, which are responsible for serious adverse effects that reduce the quality of life of these patients. However, an improvement in patient survival or quality of life after using an EUS-CPN has not been demonstrated in the current literature.

The strengths of our review are the large number of studies collected (many of them are clinical trials) with an acceptable number of patients, and many studies have demonstrated favorable results in the use of EUS-CPN in these patients, even though this technique has been performed by expert endoscopists in centers with a high volume of patients. We also present a scheme for performing this technique that shows a good applicability, and most of the complications of this technique are minor and preventable. There are several techniques for performing an EUS-CPN, all of which are valid, and the most commonly used technique is the central technique, which is known by all expert endoscopists in this field and is the technique we currently perform in our centers.

Therefore, we can conclude that the best predictor for a good response could be the celiac ganglia visualization during the EUS-CPN technique. However, any of the 4

different techniques could be offered to effectively perform an EUS-CPN with no differences in complications between the techniques based on this review.

According to this review, a universal pain reduction scale should be used to design further research and to prevent heterogeneity of the results among the studies. EUS-CPN must be performed by expert endosonographers to achieve the best approach and to have a good outcome from this technique as well as to avoid serious adverse events.

Further research is needed to clarify when to perform an EUS-CPN and whether it should be included as a first-line therapy in addition to traditional medical treatment, whether it should be performed as a prevention prior to chemotherapy or if it should be reserved for patients with uncontrolled pain that is refractory to major opioids. Well-designed RCTs are required to evaluate the improvement of pain, survival and quality of life in these patients.

Author Year	Design	N	Technique	Neurolytic agent	Pain control (follow up)	Complications
Wiersema ^[6] 1996	Retrospective	30	Bilateral	3 mL bupivacaine (0.25%) + 10 mL ethanol (98%)	88 % (10 wk)	Diarrhea 13.3%, Pain 3.3%
Gunaratnam ^[10] 2001	Prospective	58	Bilateral	3-6 mL bupivacaine (0.25%) + 10 mL ethanol (98%)	78 % (24 wk)	Pain 8.6 %
Levy ^[14] 2008	Retrospective	17	Direct	8 mL bupivacaine (0.25%) + 12 mL ethanol (99%)	94% (2-4 wk)	Hypotension 35%, pain 41% and diarrhea 16%
Sahai ^[10] 2009	Prospective	160	Central vs Bilateral	10 mL bupivacaine (0.5%) + 20 mL ethanol	45.9 % vs 70.5% (7d). p < 0.05	Bleeding 0.7 %
Sakamoto ^[13] 2010	Retrospective	67	Broad vs bilateral	3 mL lidocaine (1%) + 9 mL ethanol (98%)	Mean VAS scores 3.9 vs 2.5 (7 d) and 4.8 vs a 3.4 (30 d) p < 0.05	None
Wyse ^[7] 2011	RCT	48	Bilateral vs analgesia	10 mL bupivacaine (0.50%) + 20 mL ethanol	Likert scale reduction 28% (4 wk) + 60% (12 wk) p < 0.05	None
LeBlanc ^[12] 2011	RCT	50	Central vs bilateral	20 mL lidocaine (0.75 %) + 10 mL ethanol (98%)	69% vs 81% (61.9%)(14wk)	Hypotension 2 % pain 36 %
Iwata ^[15] 2011	Retrospective	47	Central, direct or bilateral	2-3 mL bupivacaine + 20mL ethanol	68 % (7 wk)	Hypotension 17%, diarrhea 23% and inebriation 8%
Ascunce ^[16] 2011	Retrospective	64	Bilateral	10 mL lidocaine (1%) + 20 mL ethanol (98%)	50 % (1 wk). OR 15.61 of response if celiac ganglia was detected	Hypotension 2%, pain 2% and diarrhea 23%

Wiechowska Kozłowska ^[17] 2012	Retrospective	29	Central vs bilateral	2 mL lidocaine (2%) + 20 mL ethanol (98%)	86% (1-2 wk)	Hypotonia 3.4%, pain 6.9% and diarrhea 10.3%
Téllez-Ávila ^[18] 2013	Retrospective	53	Central vs bilateral	10 mL lidocaine (1%) + 10-20 mL ethanol (98%)	48% vs 56% (4 wk)	Transitory pain 0% vs 3 %
Seicean ^[19] 2013	Retrospective	32	Central	10 mL lidocaine (1%) + 10-15 mL ethanol	75% (2 wk)	None
Doi ^[20] 2013	RCT	68	Direct vs central	1-2 mL bupivacaine (0.25-0.5 %) + 10-20 mL ethanol	73.5 % vs 45.5 % (7 d) p < 0.05	Hypotension 2.9 % vs 6 %, pain 29.4 % vs 21.2 % and diarrhea 5.9 % vs 9.1 %
Ishiwatari ^[9] 2014	Retrospective	22	Direct or bilateral	1-2 mL bupivacaine (0.5 %) + 40-60 mL ethanol or 20-25 mL fenol	83% (fenol) vs 69% (ethanol) (7d)	No differences Diarrhea 9%, hypotension 4.5%, pain 4.5 % and inebriation 4.5%
Si-Jie ^[21] 2014	Retrospective	41	Central or direct	10 mL bupivacaine (2%) + 20 mL ethanol	Pain < 3 mo improve 84% (3 d), 96% (7d) and 68% (90 d). Pain > 3 mo improve 75% (3 d), 81% (7 d) and 50% (90 d)	Hypotension 4.9 %
Minaga ^[22] 2016	Retrospective observational	112	Broad +/- direct	3 mL lidocaine (1%) + 9 mL ethanol (98%)	Pain improvement 77. 7% (1 w)+ 67.9% (4 wk)	Inebriation 8%, hypotension 4.5%, pain 3.6% and diarrhea 3.6%
Levy ^[23] 2019	RCT	110	Direct vs bilateral	4 mL bupivacaine (0.25%) + 20 mL ethanol (99%)	Pain improvement 46.2% vs 40.4% No changes on quality of life	Hypotension 11.7% vs 20%, diarrhea 10% vs 12.2%. Pain 8.3 % vs 44.9 % (p < 0.05)
